The Rains mine of the Carbon Fuel Co., which was wrecked by an explosion a few weeks ago, is now ready for official inspection. B. W. Dyer, chief mine inspector, and John Crawford, coal mine inspector, will be in charge. The State Industrial Commission had resolved that before the mine is opened for production it be completely rehabilitated; that all the stopings along entries where men are employed be permanent and of fireproof material; that dust in the mine be either loaded out or wet down, or rock dusted to such an extent as to render it inert and incapable of propagating an explosion and that the mine be examined by the coal mine inspection department of this state and pronounced safe.

Coal production in Utah for September amounted to 380,558 tons, a falling off of 5,634 tons compared with the previous month. In September, 1923, 408,536 tons was produced. The September production this year was the smallest in years. The heaviest output in September for the past five or six years was in 1922, when 489,220 tons was mined.

## VIRGINIA

The Clinchfield Coal Corporation has resumed dividends on the common stock. It will pay \$1.50 a share on Nov. 15 to stockholders of record Nov. 10. The regular quarterly dividend of 75c. a share on the preferred also has been ordered. The last previous payment on the common was  $\frac{3}{4}$  of 1 per cent, on May, 15, 1923.

The Clinchfield Coal Corporation, of Dante, has contracted with the Roberts & Schaefer Co., for the installation of R. & S. shaker loading booms to be installed at No. 2 tippie, Dante.

## WEST VIRGINIA

J. W. Powell, consulting and contracting engineer, of Charleston and Welch, W. Va., who was formerly employed for many years in the development and management of heavily pitching seams in the western part of the United States and Canada, left for Siberia Oct. 22 by the Str. Esthonia. Mr. Powell is to take the position of mine superintendent for the Autonomous Industrial Colony Kuzbus, a Russian state mining trust which operates the central and southern group of mines in the Kuznetsky Basin.

The Buckhannon River Coal Co., of Uniontown, Pa., has contracted with the Roberts & Schaefer Co., Chicago, for a new tippie of wood construction at Adrian, W. Va., which will be complete with all hoisting machinery, Marcus screens, and R. & S. loading machinery.

The Nelson Fuel Co., operating in the Greenbrier smokeless field, has just completed the installation of a water system. The water is forced by air into a main and pumped into an 80,000-gallon capacity reservoir which supplies the town of Leslie. It is freestone water and 350 gallons per minute will be produced from a depth of 190 ft.

The Fordson Coal Co., of Stone, Ky., has contracted with the Roberts & Schaefer Co., for a new steel tippie to be built at Twin Branch, W. Va. This tippie will be complete with retarding conveyor, Marcus screen and R. & S. loading booms.

Governor Morgan let it be known indirectly that he would not intervene in eviction proceedings in northern West Virginia between the miners and operators as requested by T. C. Townsend, representing the United Mine Workers. The Governor declined to take any definite action other than to refer the protest to the prosecuting attorney of Monongalia County. Governor Morgan did use his good offices in halting evictions in the Kanawha County field as a result of the visit of John L. Lewis to that section. Operators there had been evicting in accordance with a decision of the Supreme Court, but called a halt to such methods and proceeded to obtain possession of their houses through the usual court routine.

The Raleigh Wyoming Coal Co., of Charleston, has been granted authority by the Secretary of State of West Virginia to increase its authorized capital stock from \$4,100,000 to \$4,700,000.

Operators from various sections of West Virginia assembled at Washington a few days ago for a conference on proposed changes in the mining laws of West Virginia. Among those present were C. H. Jenkins, vice-president of the Hutchinson Coal Co.; Frank R. Lyon, vice-president of the Consolidation Coal Co.; Everett Drennen, president of the West Virginia Coal & Coke Co., and a number of operators from southern West Virginia. It is proposed to draft a new code of mining laws in the state.

The Pocahontas Fuel Co. will soon have two large, new plants in operation developing a 30,000-acre lease obtained from the Frick coal interests in Tazewell County, Va., and in McDowell County, W. Va. One plant is being constructed on the Jacob Fork and the other on the Dry Fork of Tug River. Cutting, cleaning and loading will be done entirely by machinery. The company expects next year to be able to mine 6,000,000 tons of smokeless coal in West Virginia.

## CANADA

A coal-weighting war has broken out in Hamilton, Ont., the dealers refusing to submit to city weighing and declining to pay back bills for it. They have their own scales that can be inspected at any time. The city is preparing to collect the bills by process of law.

Record coal outputs are being produced from the collieries of the British Empire Steel Corporation in the Glace

Bay area. The total quantity hoisted on Oct. 17 was 18,203 tons, the largest days production since October 15, 1915, on which day the output was 18,312 tons. No. 11 pit made a new mark with a production of 1,723 tons, breaking the previous record of 1,629 tons mined on July 22 last.

The miners of Alberta returned to work Oct. 20, ending the protracted strike, the men having ratified the agreement entered into by their representatives with the operators by a narrow majority. According to estimates of the Department of Labor the strike entailed a loss of about 775,000 working days and a coal production of approximately 1,500,000 tons. Now that the cost of production has been lowered by the wage reduction it is anticipated that the operators of Alberta can compete on more even terms with American producers and in addition to recovering their lost ground in Manitoba and the West, find a market in the neighboring states of North Dakota and Minnesota. The reduced cost of running also will further the projected shipping of Alberta coal to Ontario.

## Association Activities

The Kanawha Operators' Association recently held its twentieth annual meeting in Charleston, W. Va. The sessions were marked by complete harmony, all the old officers and directors being re-elected as follows: John Laing, president; D. H. Morton, vice-president; John L. Dickinson, treasurer; Duncan C. Kennedy, secretary. Directors: Col. W. M. Wiley, Col. E. O. Dana, H. L. Warner, F. O. Harris, W. C. Mitchell, F. H. Morton and C. A. Cabell. The Chesapeake & Ohio came in for high praise for the excellent transportation service rendered during the last year. The association adopted a resolution offered by Carl Scholz, vice-president of the Raleigh-Wyoming Coal Co., opposing the proposed child labor amendment to the federal constitution.

William R. Chedsey, professor of mining at Pennsylvania State College, in an address at the first fall session of the Pennsylvania Coal Mining Institute, at Johnstown Oct. 17, said he felt inclined to favor the use of high-voltage currents, explaining that he termed anything over 500 volts as high. Professor Chedsey's subject was "High Voltage vs. Low Voltage Electric Installations in Mines." He said he had no record of a death resulting from contact with a circuit of less than 220 volts and told of a fellow teacher who had to wet his fingers to feel the current of 440 volts. Of course, he said, death might result from a much less voltage, depending on the resistance of the individual. J. W. Paul, chief engineer of the U. S. Bureau of Mines at Pittsburgh, read a paper on "Explosions and Rock Dusting." Among the interested spectators at the meeting were a number of inspectors and mine foremen. E. Kent Davis, chief engineer for Peale, Peacock & Kerr, of St. Benedict, will speak at the next session of the institute, which will be held on Nov. 21.

## Industrial Notes

The Eagle Iron Works, Des Moines, Iowa, is now well established in a new and greatly enlarged manufacturing plant.

Blaw-Knox Company announces the appointment of Waldemar Dyrssen as chief engineer of the furnace equipment department and chief engineer of the forge and hammer welding department of the company. Mr. Dyrssen's experience in the steel industry has been extremely wide and comprehensive since his graduation from the Royal Technical University, Stockholm, Sweden, with the degree of Metallurgical Engineer, class of 1908.

## Traffic

### Defers Hearing on Proposal to Raise Switching Rate

The Coal, Coke & Iron Ore Committee, Central Freight Association territory, announces a postponement of the hearing on switching rates on coal, coal boulets and briquets, coke (except petroleum coke), coke breeze, coke dust and coke screenings, carloads, as shown in B. & O., C. & C. Series I.C.C. 2,429, from point of connection of B. & O. with P.R.R., Martins Ferry, Ohio, to private sidings on B. & O. R.R. within switching limits of Martins Ferry, Ohio. It has been proposed to cancel the switching rate of 13c. per net ton, minimum \$3.60 per car, and apply a rate of 76c. per net ton, as per Agent Davis' Tariff I.C.C., 43, and B. & O. Tariff I.C.C. 2306.

The hearing on this subject, which was set for Thursday, Oct. 30, 1924 (as per announcement of Public Hearing No. 34, dated Oct. 15), is postponed to Thursday, Nov. 13, 1924, at 10 a.m., in Room 606, Chamber of Commerce Building, Pittsburgh, Pa.

### Plan Better Handling of Coal At Birmingham

A meeting of traffic officials of all the coal-carrying lines in the Birmingham district and several other roads indirectly contributing equipment for the movement of coal and coke from that section was held at Birmingham, Oct. 22 and plans were evolved whereby it is thought that the mining industry will be provided with an adequate car supply through the winter and spring, a period in which the district has suffered materially in the past from shortage of cars. The meeting was attended by several coal operators, the interests of shippers being represented by S. L. Yerkes, chairman of the coal and coke committee of the Alabama Mining Institute.

### Kanawha Group Rate Sought by Winifrede Coal Co.

The Winifrede Coal Co., operating in the Kanawha district, has filed a complaint with the Interstate Commerce Commission requesting that rates from points on the Winifrede R.R. be established on the basis of rates from the Kanawha district group. It is asserted that the mines on that line are geographically, geologically and commercially and from a transportation point of view within the Kanawha group. The Chesapeake & Ohio R.R., however, has "failed, neglected or refused" to extend the group basis to the Winifrede R.R. The combination rates which must be paid, it is contended, are so excessive as to render it difficult at all times to market coal in competition with mines enjoying the group rates.

Freight rates on coke from Portsmouth, Ohio, to Wingate, Ind., which had been attacked by retailers, are reasonable, the I.C.C. has ruled.

## Obituary

**Harry B. Olmstead**, one of the best known coal operators in the Middle West, died at the Good Samaritan Hospital, Cincinnati, Oct. 24, following a short illness from pneumonia. He was 57 years of age and leaves a wife, one son and a daughter. Mr. Olmstead started in the coal business about 20 years ago in the Equitable Coal Co., which had mines on the C. & O. R.R. in the Kanawha field. Later he organized and became president of the Middle States Coal Co., which had offices in Columbus and mines at Hugar, W. Va. This company was later taken over by the Houston Coal & Coke Co., of Cincinnati, and Mr. Olmstead went with the new owners in a responsible position in the operating end of the business. He was secretary of the Williamson Operators Association.

**Edward S. Nevius**, widely known coal operator, died Oct. 19 at the home of his daughter, Mrs. Samuel Ayres, in Kansas City, Mo. Mr. Nevius was president of the Adair Coal Co., which operates mines in northeast Missouri, and formerly was president of the Nevius Coal Co., operating in Southeast Kansas fields. He was 60 years old and had lived in Kansas City more than twenty years.

**John William Wolfe**, 50 years old, treasurer of the Marmet-Halm Coke & Coal Co. and the Otto Marmet Mining Co., died suddenly at his home in Cincinnati, Oct. 16, of cerebral hemorrhage. Mr. Wolfe, who was born in Cleveland, Ohio, went to Cincinnati more than 25 years ago, and for the last eight years had been with the Marmet company. Mr. Wolfe is survived by his wife.

**Jesse Dean Stalter**, secretary of the R. Stalter Coal Co., of Columbus, Ohio, and an owner of several coal mines in the Hocking Valley district, was instantly killed when his automobile crashed against the concrete side of a viaduct in Columbus. He was seen to be driving rapidly when the car skidded with the fatal results.

**Charles Fergie**, a prominent engineer identified with the coal-mining industry, died at Montreal, Canada, Oct. 19, in his 67th year. Mr. Fergie was born in England and came to Canada in 1887, becoming manager of the Intercolonial Coal Co., Ltd., at Westville, N. S. He was afterward appointed vice-president and general manager of the company. In 1905 he was made general superintendent of mines for the Dominion Coal Co. at Sydney, N. S., holding that position until 1908, when he went to Montreal where for some years he practised as a consulting engineer. In 1914 he became president and managing director of the Intercolonial Coal Co., Ltd.

**J. J. Dobbie**, general manager of the Cumberland Coal Co., with headquarters at Douglas, W. Va., died late in October of pneumonia after an illness lasting more than a year. At the time of his death Mr. Dobbie was in his 69th year. Although a native of Maryland, Mr. Dobbie had lived in West Virginia for many years, where he had been prominent in coal mining circles. He was the father of W. Clark Dobbie, general superintendent of the New England Fuel & Transportation Co., and of Gibson Dobbie, also connected with the coal industry in the Fairmont region.

## Coming Meetings

**Illinois Mining Institute.** Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

**American Society of Mechanical Engineers.** Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**West Virginia Coal Mining Institute.** Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**Coal Mining Institute of America.** Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

**West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers.** Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

## New Equipment

### Automatic Resistance Starter Has Push Button Control

This starter is a push button control unit for squirrel-cage motors and is superior to the automatic compensator due to the smoother acceleration and greatly reduced current inrush when switched from the starting to the running tap. The graphite compression resistors are adjustable with one screw for any starting current. There are no taps to change. The motor is started by pressing the starting button of the push button station which closes

A Push Button Starts Things

After a predetermined time interval a relay closes the main line switch and the motor receives power directly from the line.

the starting clapper switch and allows the motor to accelerate with the primary resistors in the main circuit. After a fixed interval of time, the timing relay closes the main clapper switch and throws the motor on the line without opening the primary circuit and thereby short circuits the starting resistors. This switch has all the protective features of similar starters made by the Allen-Bradley Co., Milwaukee.

Such a starter as this is useful where the motor must be started and stopped from a position remote from the motor. Conveyors, belt lines and scrapers must usually be started and stopped from several different points.

### Rugged Steam Trap Designed For Extreme Pressures

A new steam trap designed for extreme pressures and temperatures has just been introduced by the Armstrong Machine Works, Three Rivers, Mich. In this latest addition to the company's line the body and cap are of high grade cast steel. All strains are removed from the castings by annealing.

The steel trap embodies the same patented basic operating principle that has been so well established in the com-

**Heavily-Built Steam Trap**

After the trap is completed it is hydraulically tested to pressures up to 3,000 lb. to insure tight joints and suitable castings. The valve parts are non-corrosive chrome steel, machined from bar stock, then heat-treated.

pany's standard type trap. The discharge is at the top so that oil and sediment are forced out whenever the trap discharges. An air port in the closed end of the inverted submerged bucket permits any air that may enter the trap to rise to the top and be released when the trap discharges.

Realizing the fierce service conditions imposed by high pressure and super-heat, the valve parts have been made particularly rugged, and throughout the trap is designed to stand up under the most severe conditions. The valve parts are non-corroding chrome steel, machined from bar stock, then heat treated. The valves are furnished with orifices suitable for pressures up to 500 and 600 lb., or higher in special cases. The cap is bolted to the body with eight to ten large bolts, depending on the size of the trap.

After the trap is completed, it is hydraulically tested to pressures up to 3,000 lb., to insure tightness of castings, joints, and valves. The steel body trap is also made for pulsating pressure service.

### **Simplified Diesel Engine Has Low Operating Cost**

An entirely new design of two-cycle, double-acting Diesel engine was recently announced by the Worthington Pump & Machinery Corp. The new engine combines a fuel economy comparable with that of the best existing types of Diesel engine, with dimensions, weight and construction cost per horsepower approaching those of reciprocating steam machinery.

Another striking and important feature of the design is the fact that, from all indications, the horsepower per cylinder can be carried to a far higher value than any yet attained in Diesel engines, thus immensely increasing the field of possible usefulness of Diesel-type power units.

The engine which has resulted from

long research will undoubtedly be of the greatest interest to industrial and mechanical engineers everywhere, as the relation of space, weight and first cost to horsepower is of importance in power plants. The new engine is characterized by simplicity of design and construction, and its initial cost per horsepower will consequently be low.

The basic principle underlying the new engine may be briefly stated to be: in the four-cycle Diesel engine one stroke in every four is a power stroke; in the two-cycle engine one stroke in two; in the new engine every stroke is a power stroke. Its working cycle, therefore, is virtually the same as that of a reciprocating steam engine.

The principle, of course, is not a novel one, but mechanical difficulties, chiefly concerned with the complicated heat stresses in the cylinder of a double-acting engine, have hitherto interfered with its successful application. The success of the Worthington design lies in the manner in which the problems of expansion and of heat removal are solved.

Once the major problem is overcome, the many advantages of the double-acting type are evident. The balance of the moving parts, for example, is simplified to a marked degree, and the weight saving, not only from the manner in which the required power per cylinder is distributed through four strokes instead of being concentrated in one, but also from the decreased provision needed to care for the momentum of moving parts, and in other ways, is obviously a big advantage.

The cylinder of the new engine might be described as composed of two single-acting cylinders, opposed end for end and working in opposite directions, their respective pistons flanged to the same rod, the scavenging and exhaust ports, cooling water circulation and expansion provisions of

the two being virtually independent of each other.

There are three fuel spray valves, one on top of the upper end of the cylinder, and two in the bottom head on opposite sides of the piston rod, entering at an angle. One of the admirable points of the design is the ingenuity with which these two valves are proportioned so as to give a uniform and symmetrical distribution of the charge around the piston rod.

The reversing mechanism, as a point of interest, is second only to the unique cylinder design. Each of the three valves has its own cam, all three are geared to the same shaft. The cams are symmetrical, and all that is necessary to reverse the running direction is to shift all three cams simultaneously through 343 deg. on the shaft. This is accomplished by a worm shaft, which in turn is actuated by an oil-operated hydraulic mechanism controlled by a four-way cock, this in turn being operated by a single lever on the manoeuvring platform.

The engine is started and stopped by a single lever, which as it is moved forward successively opens the air starting valves, then the fuel supply valves, simultaneously closing the air starting valves; the lever being then capable of being set, by a ratchet and pawl, at any desired fuel supply. To stop, all that is necessary is to throw this lever back to the stop position.

The starting and stopping lever and the reversing lever, though independent of each other in all other respects, are interlocked so that the engine must be brought to a full stop before it can be reversed. Every effort has been made, in all the auxiliary mechanism as well as in the engine proper, to secure the utmost possible simplicity both in design and operation, that can be combined with the highest efficiency and reliability.

**Two-Cycle, Double-Acting Diesel Engine**

The unit is started or stopped by a single lever which opens the air starting valves, then the fuel supply valves. Every stroke is a power stroke. Its working cycle compares favorably with that of the best type of engines.

## Outside the Four Walls

INDUSTRIES grow too largely from within. Outside progress and ideas are slow in reaching them. Manufacturers outside the industry do not know its needs, problems and opportunities; engineers in the industry do not know what has been done outside to solve their problems. The function of a technical paper is not to tell alone what the industry has done or is doing but to go a little afield and show what other industries are doing with kindred problems.

That is why *Coal Age* recently described a limestone strip pit where overburden was being removed by a steam shovel and a conveying system, and this week, describes a system of protection at the Anaconda copper mines which prevents a motorman from starting his locomotive when he is not aboard.

All the tricks and ingenuity in our industry are not of the coal man's own devising and we, mindful of that fact, are letting a few beams of inquiry circle over the surrounding fields. Where points of interest are developed we shall leave the spotlight on them for a while.

## Need for Cleaner Coal

NOTHING can convince the public that an untached piece of slate has any place in a consignment of anthracite; that it is justifiable to find such an impurity in coal that has been subjected to the cleaning process.

So long as such slate is found in small quantities or large, the feelings of the public will be unfavorable, no matter what the specifications may condone or permit. Campaigns to convert the public to a kindly perception of the difficulties of coal mining cannot make their way around that piece of slate, try as they will. Operators may tell about the vast expenditures for breakers, but that chunk of slate negatives every argument.

The impurity of industrial anthracite has made the price of that commodity low and its movement sluggish; it has given the bituminous operators a chance to get into the market; it has made a wide breach for oil. In earlier days only jigs were available for treating this fine material, and they were inefficient. Today we have better jigs and many other cleaning devices, and there is no reason why fine coal should enter the market unprepared or improperly prepared. When the freight, delivery and ash-removal rates are so large a part of the cost of the coal, careful cleaning at the mine should and does pay.

The foundation for good relations with the public lies in quality. It would pay the companies in the end to get possession of all old culm banks so as to prevent improperly cleaned culm-bank coal from reaching the market to be mixed by dishonest retailers with the better product shipped by the many ethical companies.

Too many corporations there are who regard the

terms of a specification as an end to be sought. It would be better if they entirely eliminated slate, no matter how large a tolerance the specifications might permit.

## Why Foremen Fail

AN ANALYSIS of the fatal accidents in Pennsylvania mines due to falls of rock for the first eight months of the year show that 60 per cent of these accidents occurred between the hours of 7 and 11 a.m. during which time mine officials made only 35 per cent of their visits to the working places.

As has been suggested, some of this trouble might possibly be avoided if the mine foreman who has to look after the safety of the workings made his inspections soon after the mine started. This he could do if he did not have any economic burdens, if all he had to do was to inspect and direct the manifold jobs of the mine workers so as to produce the maximum safety.

Unfortunately, in the morning, safety is not the mine foreman's first consideration, and he cannot so arrange his work that he can give it that predominance. Too often he finds that places have not been cut, the cutters having been sick or having absented themselves for other reasons. Consequently the loaders have to be shifted around, also the drivers. Some machine may have failed during the night leaving places uncut. Then again in mines with low coal about half the cars in the morning are full of rock loaded from headings during the previous night. Nothing can be done till the cars are emptied. Men must be deputed to help in this work, and a little supervision, it has been observed, helps hurry the process. Some men, also, have failed to appear so a miner has to be requisitioned to drive a locomotive or possibly a mule. A pump has failed or a flood of water has drowned out places, and men have to be shifted by reason of this untoward happening.

Furthermore there is a long line of men with complaints. They leave the presentation of their cases for either morning or evening when they will be passing the boss' office and they will be sure to find him around. Now, when the morning is still young, they find him and beset him from every side.

Thus, much of the morning passes without opportunity for activity in promoting safety unless there are safety bosses or shift bosses to take the burden and make inspections for the foremen. Even they are likely to be asked to carry messages to help the much beleaguered mine foreman get the work started, and he is indeed fortunate if all his troubles are at the mine mouth and he can avoid having to handle a difficult problem at the tippie. Cars have just been put in by the railway locomotive. In the winter some of them may be full of snow, frozen gravel, manure or sand. The foreman must provide men to clean them out. All the year round also comes the question of broken railroad cars and finding men and material for their repair.

Furthermore the cars are not always arranged to meet the needs of the mine and provisions have to be made to get the right kind and size of car spotted in the correct place so as to satisfy the market or the railroad.

Until there are more men engaged in supervision and until the foreman is prepared to delegate authority the difficulty will continue. The officials at the office should give the foreman a minimum of interference in the early morning, though that is a counsel of perfection, for they cannot get him later, if they delay getting him then.

Mechanical failures that give the mine foreman so much trouble should be removed. Cutters, loaders and daymen should be given a sense of discipline so that they will report at least, if they are going to lay off.

But all this is not as valuable as having real safety bosses who will visit the mines early and who will put safety first. It might be well to make them punch a clock inside the mine so that no orders or pleas of the mine foreman will prevent them from going to the mine at whistle blow. Otherwise they might be found coaxing a pump, removing ice, dumping rock, patching a railroad car or doing any of those many jobs which sometimes only a boss will consent to do.

### Union Hostility to Development

THE USE of loading machines has been abandoned in rooms at Orient No. 2 because the men who operated them, though paid a high wage, refused to load the cars to capacity or to do their utmost to obtain a good tonnage. They deliberately refused to live up to their contract. A loafing day is as deliberately dishonest as a short ton. The man who acts "ca'canny" at his work is as crooked as the grocer who puts sand in his sugar.

Dishonest merchants soon have to close their stores. That condition faces the mine workers of Illinois. If they will not act fairly in their business relations they will soon be without work, for they will have no companies to work for. Already the coal of western Kentucky is passing through southern Illinois to points in the middle West. A brave attempt was made by capital to put in machinery that would enable southern Illinois to stay in the market despite high wages and severe competition. Labor failed to appreciate this effort. The very expenditure of money was regarded as a proof that there were millions in the coal industry. The huge stake which was ventured was proof, they thought, that the venture could not fail.

Thus convinced the miners did their worst. As they thought that profits were inevitable and could not be jeopardized by any folly, however gross, they decided that nothing they could do could lose them their jobs. They will find only too late that by their act they have closed the door of opportunity. No one can battle with such obstacles as high wage rates, labor privileges and coal of low thermal value except by efficiency in operation. That efficiency the operators were willing to assure by the investment of millions in machinery. The mine workers on the other hand were not even willing to make an honest attempt to assist in their program. They would not even undertake to put in the contracted sixty seconds in the minute or the sixty minutes in the hour.

The mining fields are permeated with the idea that wages are not payment for work but are doles to be paid whether the work is done or not. The miners

cannot conceive that as they pay others only for services rendered, so others will pay them only in return for service. As they look for low prices so also do others. They alone cannot set the price and demand that others pay it.

The attempt to set up state lines in purchasing will not succeed, at least so long as the home state miner shows such arrogance in setting his wages and restricting his services that the purchaser loses heavily if he buys the local product. The average resident in Illinois or Ohio is little impressed by the mine worker of his state and is not willing to pay heavily to assist him in maintaining his unreasonable attitude.

### Going After Team Work

ONE WAY to reduce the cost of producing coal—a process that is essential in most coal-mining companies that expect to endure and declare dividends—is to foster greater efficiency in mine labor. One way to secure this efficiency is to prove to the men that good team work between employer and employee works both ways: it definitely benefits both. Lack of it positively damages both, especially in times like the exact present. Useless as it usually has been to preach team work in a union field, there are periods in which reasoning union miners will listen. This winter is one of them. Therefore, concerns, such as the Southern Coal, Coke & Mining Co. in Illinois, which are crusading for co-operation are on the right track and headed for the main bottom.

But nobody familiar with union field conditions underestimates the difficulty encountered. That is the reason why many a company has not even made a start. It is well known that an employer's magazine which tries to put over the lesson of team work, is going to be reviled by straw-boss officials of the union as "insidious propaganda." Messages, printed or verbal, from the head of the company intended to impress "team work" upon the men, are sneered at by the union as deceit. Continued company effort, by one plan or another, to encourage good feeling on the part of the men toward the company usually draws "don't-be-fooled-by-this-bunk" sarcasm. If this is not sufficiently counteractive, then more positive steps sometimes have been taken by the union to keep miners from "fraternizing with the enemy."

Miners too well satisfied are a menace to unionism. Men who practice "team work" and deliver a full day's labor for a full day's pay are beating somebody out of a job, as the union code would prove. So it is indeed hard to improve the efficiency of union members by winning their friendship and convincing them that they have a duty to perform toward their employer. But if a company is wholehearted and sincere in its effort it can proceed in spite of discouragement and refuse to be soured by disappointing results.

Developing a deep human interest in the welfare of its men ought to be regarded by every company as an obligation. That attitude if persistently adhered to, is bound to improve team work and raise efficiency in coal mines. The industry needs just this sort of thing.

The Illinois company is striving for it, declaring frankly that it is not out to reduce wages but to raise efficiency so as to help its men "preserve their jobs at the present wage scale if that is possible." And it appears to us that the company is making a good case. More power to it.

# Bumps and Shocks Disturb Johnson Colliery

Destructive Sudden Rock Movements Occur with Unpleasant Regularity — No Adequate Reason for Their Occurrence Is Assigned but New Theory May Be Solution of This Riddle

BY D. C. ASHMEAD

Bureau of Mines, Washington, D. C.

FOR SEVERAL years past a train of serious and fatal accidents has been occurring with discomforting regularity in the No. 2 Dunmore bed of the Johnson Colliery, operated by the Scranton Coal Co. near Dickson City, Pa. These have been the result of bumps or shock waves produced by ground or rock movement. Three of these accidents resulted in loss of life, others caused serious injuries, and yet others have occurred when no one was present in the workings affected. As usual in the case of such disturbances, the exact cause of the ground movements is impossible to determine positively but an interesting theory is advanced later in this article.

At a time when working places appeared to be normal and all other conditions safe, a sudden terrific crash would herald the occurrence of a bump or shock and one or more men might be killed or crippled. Exploration of the workings immediately following such an occurrence would show no apparent reason why such an accident should occur. Yet everything in the path of the bump would be displaced and possibly torn to pieces. Nevertheless, the roof, floor and ribs would appear to be in as sound a condition as before.

Three such accidents will be described. The first, shown in Fig. 1, occurred at the point marked 9 on the map, Fig. 4. Two men were mining the upper left-hand pillar shown in the figure. A skip had been taken from the pillar along the right side of the working place. Two cogs had been built for roof support 10 ft. apart with the mine track between them. After the bump when the rescue party arrived they found the roof, floor and ribs, so far as visual indications were concerned, in their normal condition, but the cogs instead of being 10 ft. apart were only 3½ ft. apart yet were intact. The track between them was nearly on edge instead of lying flat. Both the miner and his helper were killed.

When work had been resumed in this place after the removal of about 125 cars of coal from the pillar on which the men had been working, a channel or crevice 5 ft. wide at the top and about 2 ft. wide at the bottom was found within the pillar as shown in Fig. 1. Careful study and consideration of this phenomenon revealed no apparent reason for this fatal mishap.

## BUMPS SEEM TO OCCUR DURING PILLAR OPERATIONS

In the second accident men again were robbing a pillar. At the time the bump occurred they were in the act of loading a car. When the place was explored after the accident the roof, floor and ribs appeared to be in normal condition. Some loose coal, a comparatively small amount, was lying along one rib. The miner was dead and lying on top of the car where he had evidently been thrown or blown. His laborer, seriously injured, was lying between the car and the rib as shown in Fig. 2. This accident occurred at the

point marked 10 on the map, Fig. 4. Again no plausible cause for this mishap could be assigned.

The third accident was not fatal. A miner was driving a gangway through a pillar when the bump occurred. When the rescue party reached him, the roof, the floor, and the ribs were apparently normal, but the end of the mine track was sticking up in the air and the miner lying under it. This accident is illustrated in Fig. 3 and, as in the other two cases, no explanation for its occurrence was forthcoming.

Men who have been at work in a section where a bump or shock took place state that anything and everything in the direct line of the bump is destroyed. The direction of the force is marked. One man was walking along his room and had one foot in the air in the act of taking a step forward when a bump occurred. The only blow that he felt was one administered to the foot that was raised in taking the forward step. His leg was broken but no other part of his body was injured.

These bumps have been attributed to a number of causes. When they have been thoroughly investigated, however, the explanations advanced seem totally inadequate. It was believed by some at first that the ground movement might arise from an accumulation of gas or from the escape of air imprisoned under high pressure. No gas, however, has been found in any quantity in this coal bed. It is known to exist in the No. 2 Dunmore bed immediately above, but there are no workings

FIG. 1

FIG. 2

FIG. 3

## Figs. 1, 2 and 3—Scenes of Three Bump Accidents

In Fig. 1 the cogs shown were moved toward each other a distance of 6½ ft. yet remained intact. A wide fissure was later found in the rib. In Fig. 2 a small amount of coal was spalled from the left-hand rib. After the accident the miner was found, dead, on top of the car and his helper, badly injured, was lying between the car and the right rib. After the accident shown in Fig. 3 the miner was found lying under the uplifted end of the track. This accident was not fatal.

in this measure so far as is known and no connection or break exists between the two beds. All the other overlying measures have been first-mined on this property. In the areas where the bumps or shocks occurred tests were made to detect the presence of gas after each bump or shock had taken place, but no gas has been found. Only once has gas been detected in these workings and this will be mentioned later.

It was thought also that there might possibly be something in the strata underlying this bed that might have some effect upon these ground movements. Accordingly two boreholes, A and B, were drilled to a small bed corresponding possibly to the No. 4 Dunmore which lies below the one being worked. A section of these boreholes is shown in Table I.

Table I—Sections of Strata Penetrated by Boreholes

Borehole A			Borehole B		
Sandstone.....	24 ft.	6 in.	Sandstone.....	31 ft.	6 in.

Slate.....	2 ft.	2 in.			
Coal.....		5 in.			
Slate.....	2 ft.	6 in.			
Sandstone.....	1 ft.				

The strata penetrated by the boreholes revealed nothing that obviously could have any effect upon the occurrence of bumps or shocks.

When going into territories that have been affected by bumps, the miners have found it possible to remove props by hand, which prior to the occurrence of the bumps were wedged tightly in place. This would indi-

cate that a movement of the roof had occurred and that the weight on the prop had been lifted.

Before entering into a discussion as to the probable

cause of the accidents above enumerated, it might be well to describe in detail the conditions as they exist at present or have existed in the past. A section of the strata from the surface to the third Dunmore bed is indicated in Table II.

The property in which this mine is located slopes from the mountain down to the Lackawanna River. About 4,400 ft. from this stream occurs an anticline shown on the map, Fig. 4, by the line marked 6. About 1,600 ft. from the river occurs another anticline which is shown by the line marked 4.

The coal in this bed shows the analysis set forth in Table III. A cross-section of the coal bed at the point where the sample analyzed was taken is shown in Table IV.

Just north of the anticline marked 4 on the map at

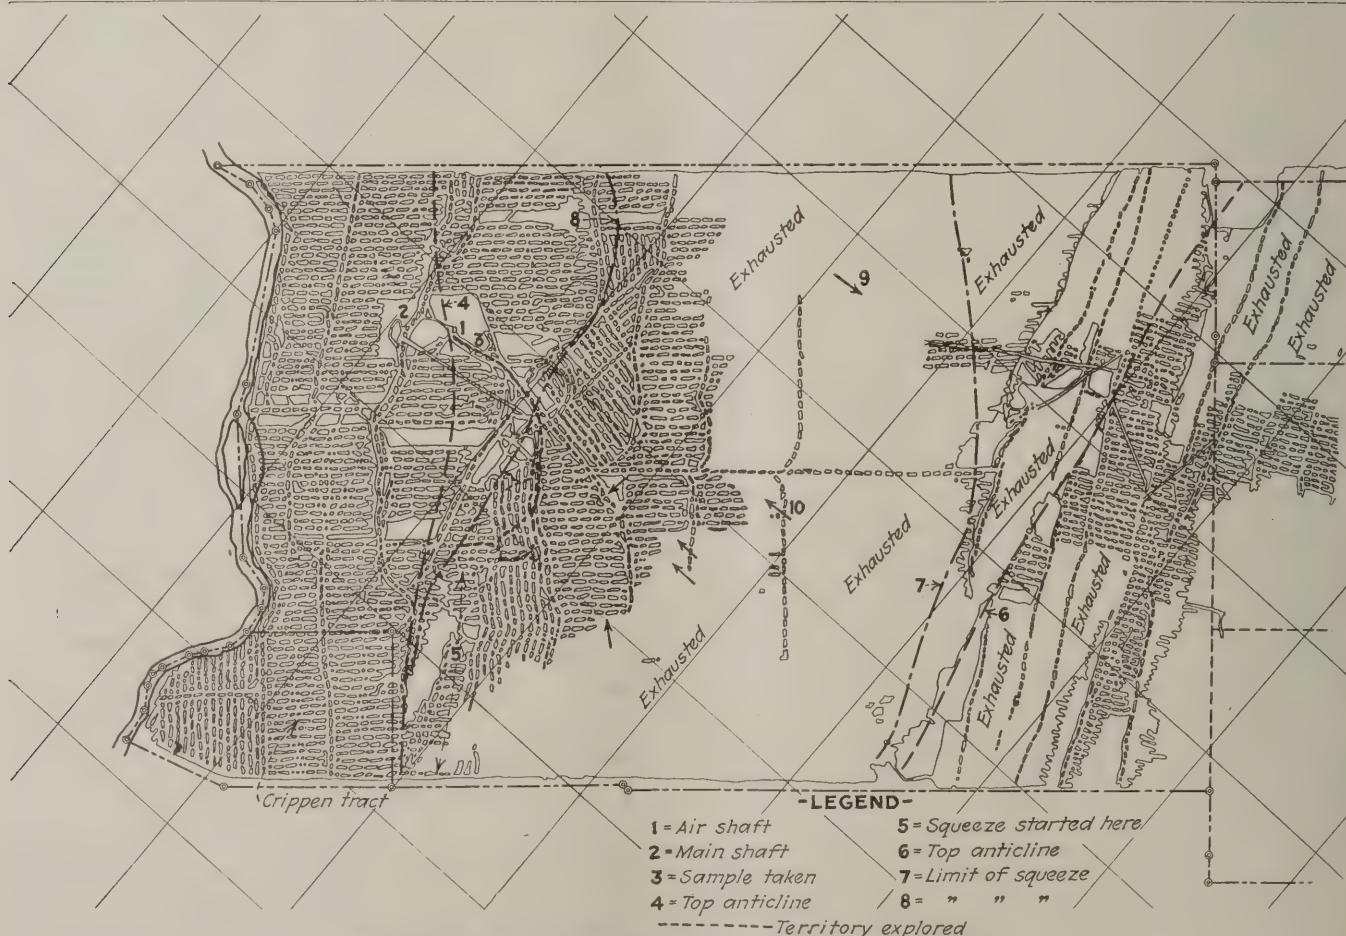

Fig. 4—Map of the Mine Workings Where Bumps Occurred

Much of the area covered by this mine has been mined out and completely exhausted. A squeeze beginning in the region marked 5 spread throughout the central portion of the mine. The locus of the bumps has also shifted until now they occur in an entirely different region from that where they were first noted. The direction of the force exerted by them, although not always clearly defined, is indicated as far as possible by the arrows.

the extreme easterly edge of the property a layer of soft graphitic material locally known as "buck" occurred immediately under the coal. After first mining, this buck squeezed out from below the pillars under the action of the 700 ft. of overburden. This movement brought a squeeze upon the coal. This squeeze began in the territory marked 5 on the map and then traveled in a northeasterly direction across

the property. Its boundaries are shown by the lines 7 and 8 on the map. A break occurred in the measures at approximately the edges of the squeezed area as shown by the lines 7 and 8. It was in the course of second mining that the series of bumps above described occurred, resulting in the loss of five lives.

#### DIRECTION OF BUMP FORCE NOT ALWAYS DETERMINATE

The indicated direction of the force of these bumps as determined by observation of the engineers is shown on the map by the various arrows. Unfortunately, it was not possible in all cases to determine this direction.

At the time the squeeze occurred in this bed between the two anticlines a heavy accumulation of gas was noted. But since this was removed there have been no indications so far as can be determined that any gas exists in this measure.

When I visited this colliery a large portion of the coal had been worked out and the accessible area that I was able to visit is shown by the dotted lines on the map. Bumps and shocks have occurred in this territory until quite recently, but none transpired during my visit.

As has been stated much second mining has been done in this property and the territory along the extreme edge between the two anticlines has been completely mined out, no pillars being left. Lately the bumps and shocks have occurred more frequently in the old workings on the western side of the property than on the eastern side.

Although considerable study has been directed toward determining the cause of these bumps nothing tangible has resulted. A new suggestion, however, recently has been offered which may throw some light upon the situation. No bumps were noted prior to the squeeze, but afterwards two breaks in the overburden occurred, extending across the property. None, however, took place on the ends, that is, along the property lines. This signifies that a great mass of rock about 3,000 ft. wide was supported at both ends but not along the sides. This left the mass resting on a coal bed where first mining had been completed and consequently one wherein roof support had been appreciably reduced.

The strata pitch at an inclination of 9 per cent toward the river and, as a consequence, have a tendency

to move in that direction. As a result two strains were set up in them. One is a tendency to move down hill causing a tension horizontally in the strata as both ends are supported. This caused the center to bow down the slope. The other is a movement of the rock mass, which is about 700 ft. thick at the thickest point, in a vertically downward direction. The vertical movement was held back by the rock being supported at both ends and, as the measures did not break, they were subjected to a stretching action producing an internal tension. This stress was modified by the tendency of the roof to move down the slope. By the robbing of the pillars roof support was removed. Strains in the overburden were thus released or set up in a different direction to those previously acting. It is believed that this release of internal stresses, which probably was instantaneous in most cases, caused the bumps.

#### RELIEF OF ROCK TENSION APPEARS TO CAUSE BUMPS

As may be readily appreciated, any slight movement, amounting to only a small fraction of an inch, in this great mass of rock would cause the instantaneous release of a terrific force. One highly important indication that the force causing these bumps and shocks was tension is the fact that after one has taken place the props were found to be loose, showing that tension in the rock mass had been released and that the strata have gone back to their normal position.

Because mining has been completed along the eastern side of the property the bumps and shocks have ceased in the eastern portion of the territory and are now occurring nearer the western side. This change in the location of the bumps indicates that the fracture of the overlying strata along the eastern edge of the property has relieved the tension existing in them and, consequently, in this section no bumps or shocks now take place. In the western side of the property, on the other hand, as no breaks have occurred in the overburden, the tension still exists and bumps and shocks continue. They will probably persist until robbing has progressed to a point where the overlying strata fracture along the western boundary.

A further indication that this theory is plausible is the fact that when a bump or shock has occurred it has been felt on the surface as great a distance as two miles or more from its origin underground. This indicates that the action of the rock movement is similar to that experienced during an earthquake.

TO GET WORK, a group of union miners bought Goat Hill mine in Ohio. To get out of the soup line, a second group of union miners accepted jobs therein. To get efficiency, the first group fired the second. To get even, the second had the first fired out of the union for disloyalty. Naturally, this shut down Goat Hill mine. Both groups were jobless again. And now to get correct answers to the great cross-word puzzle: "Who in Sam Hill is the blinkety-blank goat of Goat Hill?" we offer two tons of strictly fresh gob, a new pair of ohms, six slightly used sticks of dynamite, and other valuable prizes.

WE SOLEMNLY WARN Hon. Andy Gump, cartoon candidate for President, that his "helpless-as-a-fish-in-a-coal-mine" joke is going to beat him. Everybody knows coal mine fish are the ablest in the world. Thousands or good 7-ft. shot holes are sunk in solid coal every day by fish tails.

# Factors Which Control the Choice of a Fan

Starting Problems and Their Solution—Slip-Ring Motor Better Than Squirrel-Cage—Synchronous Motors Should Have Pull-In Equal to Full-Load Torque—Super-Synchronous Motor Designed to Meet Difficulty—Variable-Speed Fans\*

By F. L. STONE

Industrial Engineering Department, General Electric Co.,  
Schenectady, N. Y.

**T**HE LOAD characteristics of a fan are similar to those of most centrifugal apparatus, the power required by a given mine fan being approximately proportional to the cube of the speed. The normal speed of large fans varies from 75 r.p.m. to 350 r.p.m. or even higher, depending on the size and design of the fan.

The starting load of large fans differs from most other loads in that it increases rapidly with the speed. Fans cannot be bypassed advantageously. It is impractical to close the intake or outlet because of its size and the consequent pressure that would result. Furthermore, could either or both of these openings be closed, it would only reduce the load at full speed to about 75 per cent of full load. Many operators demand variable-speed fans, for they believe that at times it may be necessary to increase the speed and at other times it may be advisable to reduce it. I think, however, that mines which run their fans at constant speed delivering sufficient air at all times to keep the mine free from dangerous gases are much more numerous than those that require fans that can be run at variable speed.

With the constant-speed fan, the problem is largely one of starting. The drive may be an induction motor of the squirrel-cage type or one of the slip-ring type, geared, belted, or having a chain drive. Due to the peculiar starting conditions it would seem that the slip-ring motor has a distinct advantage over the squirrel-cage motor. If, however, the squirrel-cage motor be used, very high percentage voltage taps must be provided in the starting compensator, otherwise the motor will be thrown across the line when it is running much below full speed, thus putting an excessive stress on the apparatus and the system. With the slip-ring motor, the torque can be controlled nicely, and the speed increased gradually as required.

## SYNCHRONOUS MOTORS USED SUCCESSFULLY

Synchronous motors have been suggested for fan drive, but the pull-in torque would generally have to be 100 per cent of full-load torque if the motor is just large enough to drive the fan. To meet this requirement it would be necessary to include certain features of design which would be detrimental to other desirable characteristics in the motor. Synchronous motors have been installed, however, using a motor considerably larger than is actually necessary to drive the fan. This provides sufficient pull-in torque, but on the other hand it gives the operator a motor too large for normal service. Synchronous motors have been successfully installed on fan drives using a clutch between the rotor and the load. The motor is brought up to speed with the clutch disengaged, and the load

is picked up by the clutch. Some installations as large as 750 hp. have been so made.

To overcome the starting troubles on fans and other similar devices such as mills and crushers where there would be a decided advantage accruing from the use of a synchronous motor, one large manufacturing company has developed what it chooses to call a super-synchronous motor. This motor has, as far as the load is concerned, a starting torque equal to the breakdown torque of the motor. This is accomplished by mounting both the stator and the rotor on bearings

Fig. 1—Motor That Will Give High Pull-In Torque

The stator of this motor revolves when power is first applied to it. The brake mechanism is used to stop the rotating stator and thus permit the motor to exert its pull-out torque to start a load.

and placing a large brake around the outside of the stator.

To start a fan with such a motor the brake is released and power is applied to the stator. This begins to revolve and comes to synchronous speed with no load upon it. The field is then put on the rotor and the brake applied to the stator. When the braking effort is sufficient the stator begins to slow down, but simultaneously the rotor and load begin to accelerate, increasing in speed as the stator is slowed down. The sum of the two speeds is always equal to the synchronous speed of the motor. Finally, the stator is brought to rest and the rotor and load are at synchronous speed. I do not know of any such installation having been made on a fan, but about fifty of these machines have been installed in cement and metal mills with excellent results. One of these motors is illustrated in Fig. 1.

\*From paper, entitled "Electricity in Mines," presented at Pacific Coast Convention of American Institute of Electrical Engineers, Pasadena, Cal., Oct. 13-17.

Fig. 2—Operating Curves of Fan Drives

The ventilating system of a mine offers opportunity for application of many different types of motors. In each case the particular operating conditions and load requirements must be studied. Power-factor corrective equipment here may be quite serviceable.

The synchronous motor also lends itself much better to direct connection to the fan than the induction motor on account of the low power factor of the latter at the slow speed which the fan requires. In view of the fact that rewards are provided for high power factors by many power companies, it would not be surprising, as the work of electrification proceeds, to see many more synchronous-motor drives for fans installed.

Variable-speed fans present an added problem. The starting conditions are similar to those of the constant-speed fan, but we have the additional problem of the

Fig. 3—Operate Fan Motors Near Full Load

The power factor of an induction motor when operated at slow speed is unusually poor. Its use is therefore best suited to fans which always run at the same speed. These curves compare various types of drives.

variable-speed control. Where two or possibly three fixed speeds are sufficient and these speeds are some common fraction of full speed, such as one-half and three-quarters, a pole-changing squirrel-cage induction motor may be used. On large drives, however, wherever variable speed is required, intermediate speeds are usually necessary. This makes the use of a squirrel-cage motor impossible.

For variable-speed fan drives, we have the slip-ring motor with controller and resistance, the brush-lifting alternating-current motor, the Scherbius and Cramer systems of drive with various modifications and perhaps the Ward-Leonard control.

#### OPERATING CURVES COMPARE MOTORS

Fig. 2 shows the power required at the fan shaft for a given fan at various speeds from minimum to maximum. On the same sheet are shown the powers consumed to drive this fan at the various speeds using first the slip-ring induction motor, second the brush-

Fig. 4—High Power Factor Type of Fan Drive

This motor is designed to give good power factor even when operated at slow speed. By shifting the brushes on a specially designed commutator many different speeds are obtainable.

lifting motor and third the Ward-Leonard system of control. As the power factor of the slip-ring motor falls quite rapidly at light loads, curves are also shown in Fig. 3 giving the kilovolt-ampere input under the same conditions. Other sizes of fans and other speed variations may change the relative values of these curves. It is only necessary to capitalize the saving of one over the other to determine which is the cheapest form of drive.

Reliability is, in many installations the controlling factor in the choice. The slip-ring motor perhaps has a little the best of this argument, there being only one motor involved and no commutators or other mechanism beyond the control and resistance. The other systems, however, are reliable and have been installed on a large number of fans.

The curves shown in Figs. 2 and 3 do not take into account the efficiency of the fan proper. This efficiency is just as important as the efficiency of the motor. For instance, the majority of fans will increase in efficiency up to a certain speed and beyond this speed the efficiency falls off rapidly. Thus a most efficient motor might be selected, but because the fan was being operated at a speed at which it was inefficient the

overall efficiency of the installation might be low. The prospective purchaser is strongly urged to make a thorough analysis of his fan and drive requirements before obligating himself beyond recall. A small percentage difference in efficiency is much more serious in the case of a fan than in almost any other motor application about the mine. The fan runs continuously and therefore the kilowatt-hours consumed pile up at an amazing rate so that a small per cent saved by improving the efficiency of this drive nets the operator a large return over the year.

#### AUTOMATIC OPERATION FOR FAN DRIVES

In this day of automatics, fan drives have received their share of attention. They may now be built to start automatically upon the return of power after an interruption and to shut down and notify the officials in case of hot bearings or excessive temperatures in any part of the apparatus. They can be started and stopped by remote control.

Motor-driven fans, if properly designed and installed, are thoroughly reliable and economical pieces of machinery. The fan load is ideal from the power-supply standpoint. It is usually steady for 24 hr. a day and seven days a week. From the operator's standpoint it helps materially to improve his load factor. Fig. 4 shows a brush-shifting motor directly coupled to a high-speed fan.

## Britain Drastically Revises Its Shotfiring Rules

**Shotfirers Must Be Certified and Must Not Be Paid  
Tonnage Rate—Coal Dust Must Be Treated  
Before Shooting**

CONVINCED by the explosions at the Haig, St. Helens, East Pleau and Wheldale mines that the laws relating to shot-firing need amendment, the Board of Trade of Great Britain, that has what amounts to legislative powers, has amended the "Explosives in Coal Mines Order" of Sept. 1, 1923, and the rules now provide that persons engaged in shotfiring must be competent and appointed in writing by the manager to perform that task. No shot shall be fired by any other person.

Men are disqualified if their wages depend on the tonnage of coal gotten, and no shotfirer not employed in that manner prior to the order being put in force shall be qualified for appointment unless he is the holder of a first- or second-class certificate of competency under the Coal Mines Act, 1911, or is 23 years of age or upwards and has had at least five years practical experience underground in a mine of which not less than two years have been at the face of the workings of a mine. Furthermore he must have obtained like certificates, as to his ability to make accurate tests for flammable gas and as to his eyesight, as are required in the case of firemen, examiners or deputies by section 15 of the Act. However, where flammable gas is not known no such requirements shall be made.

And now as to shots, the order says that no shot shall be fired unless, immediately before the shot is fired, the shotfirer has examined, with a locked flame safety lamp of approved type or with other apparatus approved for the purpose by the Board of Trade, the

place where the shot is to be fired and all contiguous accessible places within a radius of 20 yd. from the place and has found them clear of flammable gas and in all respects safe for firing.

This examination should be extended to ascertain if any flammable gas is issuing from the shothole or from any break within a radius of 20 yd. If within that radius there is any cavity that may contain flammable gas and cannot be examined, or any break where an examination cannot be made for flammable gas issuing from it (other than inaccessible cavities or breaks in the gob, goaf or waste) the shot shall not be fired. These requirements also shall not apply to mines in which flammable gas is not known.

#### THOROUGH DUST TREATMENT REQUIRED

Another provision requires that no shot shall be fired until the place, floor, roof and sides of all contiguous accessible places within a radius of 5 yd. from the place where the shot is to be fired have been thoroughly treated with incombustible dust or with water or in such other manner as the Board of Trade may approve. If the place where the shot is to be fired is in or near the coal face and not more than 10 yd. from a road which has been so treated under the General Regulations of July 30, 1920, the treatment shall, in addition, be made continuous from the road to the shothole.

There are exceptions, however, that come into effect if the manager or undermanager has satisfied himself as regards any part of the mine that the natural conditions for the time being in respect to the presence of incombustible dust and moisture render any coal dust harmless. In that case he may give the shotfirers concerned special permission in writing to dispense with the foregoing precautions in that part of the mine. But to make it clear that the precautions are not being taken, a copy of every such permission must be posted at the head of the shaft and the copy must be forwarded to the inspector of the division at least seven full days before the permission becomes operative. If any question arises as to what dust is harmless the decision of the inspector of any division shall be final, subject to an appeal to the Chief Inspector of Mines, and pending the settlement of the question no permission given shall be operative without the consent of the inspector of the division.

#### FORBIDS UNNECESSARY SHOOTING

Furthermore it is provided that two or more shots shall not be fired in the same place simultaneously and that if two or more shotholes shall have been placed in such a manner that the firing of one shot would be likely to relieve any part of the work to be done by another, each shot shall be fired before any other of the shotholes is charged.

However, if the shots are placed in a longwall face and are fired between shifts and for their shooting require more time than the working shift affords this rule does not apply.

These rules about the shooting of two or more shots concurrently or charging two or more at one time when one depends for its action partly on the work of another does not apply in the driving of rock headings or in sinking shafts provided that the regular precautions are taken and that in rock headings no more than three shots are fired simultaneously unless they are fired electrically in series.

# Planning an Efficient Rock Pulverizing Unit

It Should Have a Preliminary Crusher, Possibly a Dryer, and a Pulverizer of at Least 1 Ton Per Hour Capacity Producing Dust of 95 Per Cent 60-Mesh and 60 Per Cent 200-Mesh Fineness

BY L. H. STURTEVANT  
Boston, Mass.

SO MUCH interest now centers on rock dusting of coal mines that many mining men are considering the vexing question: How fine should we grind rock for our use? What sort of equipment should we install? How elaborate a plant is essential? To aid in the solution of these problems the opinion is here expressed that for an average mine, 95 per cent of the rock dust produced should be of 60-mesh fineness and 60 per cent of it should pass through a 200-mesh screen. The preparation equipment to produce it should include a preliminary crusher, possibly a dryer, and a pulverizer of at least one ton per hour capacity driven at slow speed by a motor of about 25-hp. rating. The whole plant might be housed in an 18x24-ft. building. The reasons for adopting such equipment will be explained later in this article.

Experience both here and abroad has proven conclusively that the principle involved in protecting coal mines with rock dust is a sound one and should be adopted wherever coal is produced by underground mining methods. This should be done not only on humanitarian grounds but for economic reasons as well—saving the expense caused by explosions, reducing the high cost of insurance and for other considerations.

Many varieties of rock when suitably pulverized are adapted to this purpose. In order to be suitable, however, such rock should be free from carbonaceous matter and contain only a small amount of free silica, which is injurious to the health of workers. It should preferably be of a light color so as to aid in mine illumination, but above all it should be ground to a fineness sufficient so that when distributed throughout the mine it may be thrown into a cloud in the air under the action of an explosive wave. Limestone, gypsum, anhydrite, talc and shale, provided they are free from sand or flint, answer the purpose admirably.

Rock after pulverization should be applied to all haulage roads, cross entries, secondary entries, room necks, rooms, airways and, in fact, wherever coal dust lodges. It should also be installed in barriers at the mouths of panels, cross entries and other strategic positions. The amount that should be applied is that quantity necessary to dilute the coal dust already deposited to such an extent that the combustible content of the resulting mixture will not exceed 45 per cent. After the first application of rock dust careful sampling will determine the proper interval of time that should elapse between redustings. It also will show the amount of dust required to reduce the combustible content to the permissible maximum.

In gaseous operations from 5 to 10 per cent excess of rock dust should be applied for each per cent of methane present in the mine atmosphere. No definite rule can be laid down as to the actual quantity of dust required per square foot of mine area. But for the average operation a grinding plant producing from 1 to 2 tons per hour should be of ample size. As a matter

of fact this is about the smallest reliable grinding plant procurable. Mines usually require from 2 to 3 tons of dust per mile of heading or room treated.

## ONE TO TWO TONS PER HOUR SHOULD BE ENOUGH

Should the capacity of such a grinding plant be too great for individual requirements if operated constantly, it might be run a sufficient portion of the time to produce the necessary dust rather than to install an inferior equipment or one not rugged or strong enough to withstand continuous service. One attendant to feed the rock to the primary crusher is all that should be necessary to operate a unit of this or even a larger size.

Fig. 1—Jaw Crusher Making First Reduction

Unless the rock comes to the crushing plant in small pieces it is advisable to pass it through the crusher as a first operation. Such a crusher as here shown reduces the rock to suitable size for the pulverizer and saves the labor necessary to break down the rock by means of hand sledges.

If the rock coming to the crusher plant contains much over 2 per cent of moisture it sometimes becomes necessary to install and operate a dryer between the crusher and pulverizer.

Some difference of opinion has been expressed regarding the fineness to which rock dust should be ground. English coal operators specify that 100 per cent shall pass a 28-mesh screen and that 50 per cent shall pass a 250 mesh screen. American opinion regarding this requirement varies from 100 per cent passing 20-mesh screen, of which 50 per cent should pass a 200-mesh, to 100 per cent passing a 50-mesh screen, and 70 per cent passing a 200-mesh sieve. Some recommendations in fact specify much finer dust than has been named.

There seems to be every reason to believe that the finer the dust is ground the more readily can it be applied and the more easily will it be raised in the air along with the coal dust to prevent the propagation of flame. The finer the dust is ground, however, the more costly it is to produce. So that all things considered it is believed that 95 per cent passing a 60-mesh screen, of which approximately 60 per cent will pass a 200-mesh screen, is a practical fineness. This is also one that is reasonably cheap to produce, easy and effec-

Fig. 2—Pulverizer Giving Ready Access to Internal Parts

In this machine material to be ground is fed to the inner surface of a steel ring against which it is held by centrifugal force. The heavy rollers shown to the right are pressed against the material by means of springs. As they never touch the steel raceway they grind the rock by crushing it upon itself.

tive in application and efficient in preventing catastrophies.

While different rocks vary greatly in the amount of 200-mesh dust yielded in the pulverizer, it is believed that in most instances it will be necessary to grind to at least 50 or 60 mesh, in order to secure the required amount of 200-mesh "floats" in the product. Consequently it would be unwise to install any equipment that would not meet these specifications.

Any new proposition offering remunerative possibilities brings forth innumerable devices guaranteed to fulfill all requirements at small cost. Rock dusting will be no exception to this general rule. As a matter of fact the specifications above outlined form a definite proposition which is not altogether unusual. Standard equipment therefore can and should be utilized if long experience in rock grinding is to be taken advantage of.

Fig. 3—Independent Vibrating Screen

After the material has been reduced to proper size in the crusher it is passed over a screen of this kind or subjected to air separation. Either device separates the material of proper fineness from the oversize which is returned to the crusher for re-treatment, while the dust goes to a suitable storage bin. This latter device is inclosed and made dust-tight.

Certain lines of pulverizers are already on the market which represent many years of experience and which are favorably known throughout the world. Several varieties and types of grinding machines of this kind have been developed. These embrace devices ranging all the way from the ancient millstone down to the most modern hammer and roll mill. They can be had in high, low and medium speeds and consequently any reasonable requirement may be fulfilled without difficulty.

#### PULVERIZATION TO 60 OR 80 MESH DESIRABLE

After a careful study of the situation and the results desired, particularly in view of the great desirability of securing a dust of 60 mesh or finer, in order to save installation costs as well as in view of probable government regulations as to fineness, it would appear wise to install a pulverizer that attains its maximum effi-

Fig. 4—Longitudinal Section of a Dust Plant

All equipment necessary to fulfill the dust-grinding requirements of the ordinary mine, including crusher, elevators, pulverizer, screen, spouting and bins, can be housed in a building 18x24 ft. in plan and 15 ft. high to the square. If a drier must be interposed between crusher and pulverizer more space will be necessary.

ciency when producing from 60- to 80-mesh material. At the same time, however, the machine should consume a minimum of power, require only occasional repairs and be as nearly foolproof as possible so that it may be operated by any intelligent man. To meet these requirements slow speed is a primary essential, for this in itself signifies durability. An example of a machine of this type is the open door ring-roll mill, shown in Fig. 2. This machine is fitted with a ring revolving at a comparatively slow speed onto the inner surface of which incoming material is fed. Here it is held by centrifugal force resulting from the ring's rotation.

Upon this layer of material either one or three rolls are strongly pressed and are revolved by the friction against the material itself. They never come in contact with the inner surface of the ring and as a result the material is crushed by pressure upon itself and is free to discharge from either side of the ring into an elevator by which it is carried to an independent inclined screen electrically vibrated, or to an air separator.

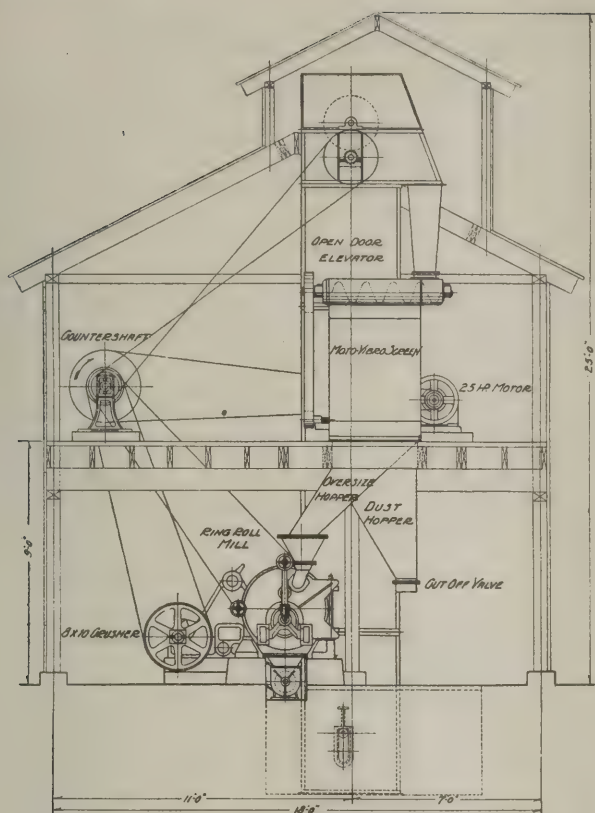

Fig. 5—Transverse Section of Dust Plant

The extremely simple arrangement of machinery is here apparent. All the various machines may be driven from one counter-shaft. One man, who feeds the rock to the crusher, is all that is required to operate a plant of this type.

Either machine will remove the fine material made by the pulverizer, the oversize being returned to the mill for repulverization.

When treated by this method a reasonable amount of moisture in the rock does not seriously affect the grinding capacity of the plant. Furthermore, each machine working independently of the other operates with maximum efficiency. Each is completely accessible for inspection or repair. Inasmuch as the finished product must necessarily be elevated in any case in order to be placed in a hopper or bin at sufficient height to permit its easy withdrawal when needed, no additional expense is necessary for carrying it to such a container, as the discharge from the screen or air separator leads directly to it.

#### ONLY 25 HP. REQUIRED FOR ROCK PULVERIZATION

Such a plant is capable of reducing all the rock to 20 mesh and finer. On the other hand it can be made to produce a 300-mesh product by simple adjustment. Consequently, through the installation of such a pulverizing unit at the present time, any future regulations by government agencies either national or state can readily be complied with.

Whatever pulverizer is used, a preliminary crusher should be installed to reduce the initial rock to suitable size and thus save the amount of labor necessary for sledging large pieces. A crusher having a jaw opening of not less than 8x10 in. should be employed, as this is about the minimum size that will eliminate hand labor. A complete plant, therefore, will consist of one 8x10-in. crusher, one No. 0 Ring-Roll mill, or its equivalent, one elevator and one vibrating screen or an air separator, of a capacity of from 1 to 3 tons per hour

depending upon the rock treated and the fineness of the finished output desired. Such a plant would require a motor of about 25 hp. for its efficient operation. On the other hand a unit might be installed with any reasonable size of machines or any reasonable capacity, grinding to almost any fineness. If no dryer is necessary between crusher and pulverizer a plant of the size I have mentioned could be placed in a building approximately 18x24 ft. in plan with a height of 15 ft. to the square.

Naturally other equipment not mentioned here should be installed in any plant of this kind. This would include such items as airtight spouts, hoppers and connections, electric wiring, possibly transformers and the like. Standard design for such equipment has, however, been perfected and demands for these various items, including even buildings, labor supervision, erection, installation and preliminary operation, can be filled by a single company. The entire responsibility for both design and results may thus be confined to one concern of wide experience in the manufacture and operation of crushing and grinding machinery.

## Europe Is Developing Some New Methods for Washing Coal

Most Promising Ones Employ Pulsating Jig with Double Rock Discharge, an Oil Froth in Vacuum or an Air Suction Dryer

BY C. H. S. TUPHOLME  
London, England

ONE NATURAL result of the shortage and high price of coal in Europe has been the development of a number of coal-washing devices. Many of these have not yet progressed beyond the experimental stage, but the colliery owner who would keep pace with modern progress in coal-cleaning methods must devote a large portion of his day to digesting reports, articles and patent specifications in order to be in a position to distinguish between the practical and the purely theoretical. One or two processes, however, are now being tried out that promise some degree of commercial success.

One of these, according to the Ateliers de Construction de la Basse Sambre, of Belgium, possesses certain marked improvements over the general run of pulsating or plunger-type washers. In this device a single screen is located at some distance from both the front and rear walls of the washer body, the object of the new machine being to secure a regular discharge of the heavier refuse immediately at the rear of the screen, the discharge of the lighter pieces of rock at the front of the screen, and a uniform operation of the plant irrespective of the rate of feed of the raw coal.

#### ADJUSTABLE GATES CONTROL ROCK DISCHARGE

These results are achieved by providing gates of adjustable height at either end of the screen. The heaviest pieces of rock are discharged automatically at the end near the pulsating plunger while the lighter refuse is discharged similarly at the other end of the screen. These two classes of rock form a barrier against the coal in front of each of the gates and pass into separate compartments filled with water to the same level as that in the screen compartment. Thus the washer is never allowed to run dry. The washed

coal is discharged over the barrier composed of the lighter rock.

Fig. 1 is a cross-section of the washer, and Fig. 2 a partial section along the line A-B of Fig. 1, looking toward the front of the washer. Feed reaches the machine by way of the chute 1, located above the plunger chamber. This delivers the raw coal to the washing bed on the screen, 3. Communication between the piston chamber and the screen is made by way of the openings, 10.

#### COAL DISCHARGED AUTOMATICALLY

Discharge of the coal is effected automatically by the adjustable gate, 2. This is approximately V-shaped with one branch vertical, the height being controllable for varying the thickness of the bed on the screen. The heavier pieces of rock are separated immediately at the rear end of the screen and pass out under the adjustable gate, 4. Such pieces form a barrier the height of which is determined by that of the gate in front of the lip, 6.

Each piece of rock as it arrives at the gate drives out another at the top which then drops into the funnel-shaped pipe, 7, by which it is discharged to the bucket elevator 8 which withdraws it from the machine. Inasmuch as the heavy pieces of rock are discharged immediately on entering the machine, a more homogeneous washing bed and more uniform water pulsations are secured. This results in an improved yield.

Since the gates extend across the full width of the washer the liability of the machine becoming obstructed by foreign bodies is eliminated. Material passing through the screen, 3, is discharged at the bottom of the washer by way of the pipe, 9.

The lighter refuse, which ultimately is rewashed, is

discharged at the front end of the screen by passing under a gate, identical with that at the rear, and passing by way of the pipe 11 to the bucket elevator, 12. Since the products are discharged into separate compartments which are themselves filled with water to the same level as the washer itself, the main machine cannot be emptied in the course of normal operation.

The advantages of this type of washer may be summarized as follows: (1) The discharge of the heavier rock particles is effected at the rear end of the screen so that wear upon it is minimized. (2) The rock chutes have the same width as the washer so that a piece of iron or other foreign material can easily pass away. (3) The quality of the finished product is consistent irrespective of the feed of raw coal because the outlets are so dimensioned that the washer does not become choked with waste material. (4) Washing is regulated by adjusting the gates to a height that will yield the desired results.

#### COAL TRAPPED IN OIL-FROTH CREATED IN VACUUM

In another process, invented by a British engineer, an oil is employed which coats the coal particles and permits their separation from waste. This method is applicable to the separation of coal from finely-divided refuse through the medium of a froth in which the coal particles are trapped but from which the gangue is excluded.

Finely crushed material is mixed with water and an oil miscible with water such as cresol, paraffin oil, or wood tar. The mixture is then violently agitated in a closed chamber within which a partial vacuum is maintained. In some cases also air or gas is introduced into the mixture. By this means the coal particles become thoroughly coated with oil in which condition they are discharged to a tank containing water under atmospheric pressure. Here the coal particles entrapped in bubbles of froth rise to the surface while the rock particles settle to the bottom. The agitator employed in this process is a simple rotary stirrer.

#### CHEMICAL REAGENTS ENTIRELY UNNECESSARY

The advantages claimed for this process are: The elimination of all chemical reagents required in similar processes to effect a thorough wetting of impurities and prevent their rising into the froth with the coal. The reagents most commonly used in processes of this kind are, sodium silicate, caustic soda or similar substances of an alkaline nature. In the method just described such reagents are unnecessary because of the partial vacuum under which agitation is conducted. By this means the small rock particles are as thoroughly bared and wetted as in processes employing an alkaline reagent.

Still a third method of fine coal recovery is a German invention and is intended to effect the reclamation of fine coal from the sludge of colliery washeries. In most cases considerable difficulty attends the drying and recovery of such fine coal as it forms a compact mass that holds water tenaciously.

In this process the fine material is flushed onto a perforated floor or platform, in many instances in successive layers, the finest material being on the top. Creating a partial vacuum above the bed of material thus formed draws air upward through it. By this means the fine material can be dried to any desired degree.

Figs. 1 and 2—Sections of New Jig

This washing device is peculiar in that it has two points or gates through which slate and other refuse is discharged. One of these is at the front of the machine and through it the heavier and larger pieces of rock escape. The other is at the rear of the screen and through it the smaller and lighter pieces of refuse find their way. This relieves wear on the screen as well as resulting in a cleaner and more uniform product.

# No Unnecessary Pipe Fittings in This Pump Station

Single-Stage Centrifugal Pumps Are Connected in Series — Units Rated 400 H P., 4,200 Gallons Per Minute, 285-Ft. Head — Brick Lined Duct Connects Pump House with 60-Acre Sump

BY J. H. EDWARDS  
Associate Editor, *Coal Age*  
Huntington, W. Va.

**A**BOUT EIGHTEEN months ago the Keystone Coal and Coke Co., of Greensburg, Pa., put into operation the first two units of its new central pump station. Simplicity and reliability were the prime factors governing the design and installation. The plant has attracted attention not only because of the mechanical features but also because of its large sump area, and the extensive territory drained.

The new pumping station is located at the Crows Nest mine which is at the lowest point of the Greensburg basin and very close to its center. This coal area is about twelve miles long, and its greatest width is approximately four miles. All mines except one in this Greensburg district are operated by the Keystone Coal and Coke Co., and in the territory the Pittsburgh seam, which is the one being mined, pitches gradually from all directions toward the center. This affords natural drainage to the central pump station from all mine workings, some of which are six miles distant. Before plans were made for a new pumping plant the possibility of a tunnel to secure natural drainage was considered, however, this was found impractical due to the fact that the method would require a tunnel over eight miles in length.

Although located at a point which makes it possible, it was not the intention to have the new plant displace any of the other six pumping stations, but rather to have it act as a reinforcement to all. It regularly handles the water from the Crows Nest mine and, in addition, any surplus from the other mines which may be caused by excessive inflow or failure of other pumps to operate.

The large sump capacity at the new pump station is a noteworthy feature. Nearly sixty acres of mined-

out area is used for this purpose. The station is located some distance from the low point, a duct 10 ft. wide and 1,500 ft. long being used to carry the water by gravity to the sump which supplies the large centrifugal pumps.

The pumproom was designed for an ultimate installation of five units. However, up to the present, space for only four is provided and of these only two have been installed. The walls of the sump, pump room, and check valve compartments are built of brick, 13 in. thick except in the compartments where 9 in. was considered sufficient. Concrete was used for the bottom of the sump and for the floor and foundation in the pump room. The roof is made of brick laid between 4-in. steel I-beams which in turn are supported by 12-in. I-beams, 20 ft. long, set about 5 ft. apart. The room was made 13 ft. high, this in order to accommodate a traveling crane the runway of which is supported by steel brackets set in the brick side walls.

## ARRANGEMENT FACILITATES REPAIRING

Direct-connected, motor-driven centrifugal pumps are used. These units are rated as follows: 4,200 gallons per minute, 285-ft. head, 1,150 r.p.m., 400 hp., 77 per cent pump efficiency. The motors are 2,300-volt, squirrel cage, 40-degree type and are controlled by hand-operated auto-transformer starters, equipped with ammeters for checking pump performance. In keeping with the simplicity and reliability of the whole design, multi-stage pumps are not used, but instead each unit is made up of two single-stage pumps with the shafts connected by flexible couplings so as to be driven by the one motor. This arrangement facilitates repairing and by keeping in stock one single-stage pump almost

### Pump Station Top Equipment

The object "A," lying on the wooden cover of the brick borehole top, is a 6-ft. section of corroded 14-in. casing which was forced out through a 14-in. elbow and discharged into the sluiceway. This casing, which was of extra heavy steel pipe, has been reduced to a mere shell in less than two years. Wires leading to the power borehole can be seen at the right of the steel structure.

### Pumps at New Station

Two interchangeable single-stage centrifugal pumps connected together make up each unit. There is a good sized opening around the discharge line into the valve stall, allowing ample room for making repairs. Plans call for a room 129 ft. long, accommodating five pumps. Space for four has been completed, but only two units are installed.

certain protection is provided against long shut down due to a pump failure.

The high acid content of the mine water made necessary special precautions to minimize the effect of corrosion. The pumps are built of acid-resisting bronze. Wood lined 14-in. cast-iron pipe is used between the pump discharge and the bronze spud which enters the borehole. Plain cast-iron pipe forms the 14-in. suction lines. The bronze spud mentioned is 6 ft. long, and somewhat over 4 ft. of it is cemented into the rock.

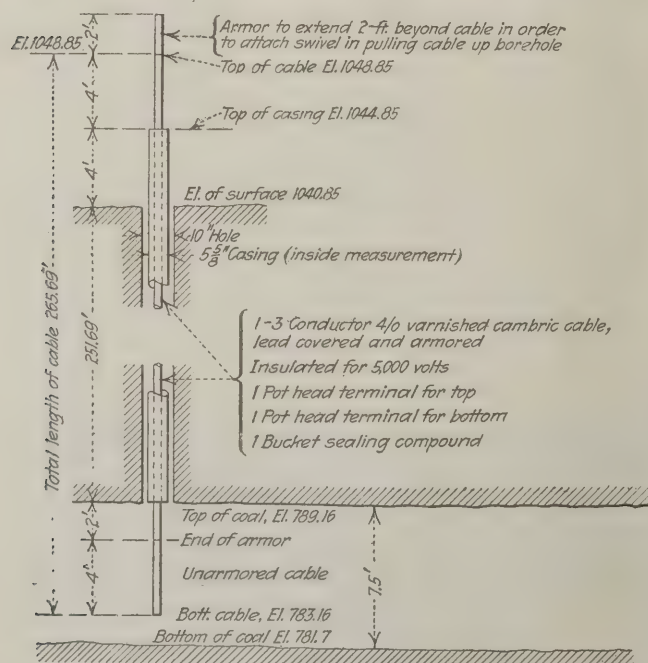

The two 256-ft. discharge holes were drilled approximately 18 in. in diameter, then cased with 14-in. extra heavy steel pipe clear down to the bronze spud. The

casing was then surrounded by concrete for the entire length, providing a smooth concrete duct to serve if the casing rusts away. Extra heavy pipe was used as casing for the sole reason that it was on hand, having been removed from discontinued power plants.

When the photographs here reproduced were being taken it was a surprise to find a 6-ft. length of mere shell of the 14-in. pipe lying in the wooden sluiceway which conducts the discharged mine water to a near-by creek. This shell was so thin that the force of the water had crushed and bent it sufficiently to make it pass out through the elbow of 14-in. radius at the top of the hole. The complete destruction of this extra heavy pipe after less than two years' service indicates the acid condition encountered.

Returning to a consideration of the pump room arrangement we see several features of interest. All foot valves, gate valves and the like are eliminated from the main lines. The only ones used are special, heavy-type check valves connected in the discharge. This check valve of each unit is located in a separate brick compartment, as a precaution against possible wetting of the electrical equipment in case of a break. In the valve compartment all draw slate and loose material was taken down so that the bronze borehole spud could be cemented into solid sandstone.

Priming of the 14-in. centrifugal pumps is accomplished by a 3-hp. chain-driven, vertical vacuum pump. It is the intention to equip the station with another

### Power Borehole and Cable Dimensions

This sketch was made from the drawing and bill of material which was submitted to the manufacturer who furnished the cable and pot head. Note that the details of armor length at the cable ends are carefully specified.

### Cable Pot Head

A thick coating of pitch covers the pot head on this 2,300-volt armored cable and its junction with the 5 3/8-in. casing.

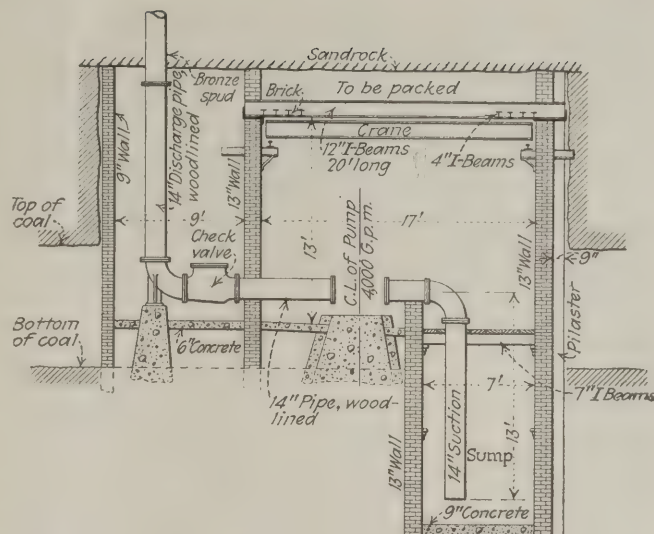

similar pump at a later date after one or two more of the large units are installed. The average suction head on the pumps is 10 ft., and the discharge 259 ft., making a total of 269 ft., not including the added resistance due to friction.

As mentioned before, each motor starting panel is equipped with an ammeter. The scale of each is marked with a red line at the point of normal efficiency for that pump. Assuming that the regular current taken by a motor is 25 amp., then a change in demand to 22 or 23 amp. indicates a decrease in pumping efficiency probably due to a worn pump or pipe line obstruction. Such meters are being used in the older pumping stations as well as in the one here described.

Electric power for the two 400-hp. motors is carried down through a borehole at 2,300 volts. The 25,000-volt to 2,300-volt step-down transformers are located within a few feet of the hole. A three-conductor, No. 0000 B. & S. gage varnished cambric, lead covered and armored cable is used, and is suspended from a pot head which in turn is supported by being mounted directly on top of the 5½-in. casing. The borehole, which is 251 ft. deep, was drilled 10 in. in diameter to allow space for a 2-in. thickness of concrete which was poured in the hole to surround the casing for its entire length.

The upper pot head, being out in the weather, was covered with a thick coating of pitch to prevent water

#### There Is Only One Valve Per Unit Here

The check valve is in a separate brick compartment. This minimizes the chance of wetting the electrical equipment, should the valve body break. The 13-ft. ceiling allows ample clearance for taking full advantage of the overhead traveling crane when repairing equipment. The roof is made of brick laid between 4-in. I-beams. The weight is taken by 12-in. I-beams set about 5 ft. apart, the roof span being 17 ft.

from entering the casing. Apparently every reasonable precaution has been taken to insure reliability; however, it is the intention to install a duplicate cable.

#### Substations and Pumps Are Co-ordinated To the Best Advantage

If the pumping load of a mine can be applied during off-peak periods large savings can be realized in power bills. At the Keystone Coal and Coke Co.'s mines every effort has been made to do the pumping either during the night or when power demands are low during the day. Accurate records are kept at all the substations to determine when the pumps can be run and yet not unduly raise the maximum demand.

#### Bronze Pumps and Wood-Lined Pipes Necessary for this Water

Each pump consists of two single-stage units designed so that they can be repaired as easily as possible. There is no need to disturb the whole pump when any part must be examined or replaced. Squirrel cage motors drive each of the two pumps now installed, thus the control equipment has been made simple and easy to operate. A vacuum pump is used to prime the units whenever the sump must be pumped down.

In order to check present performance and to predict future requirements, daily records are made of rainfall and pumping. The pump station records, which are kept of the new central plant and of the old stations as well, include gallons pumped, also total hours and actual periods of the day each pump is in use. Table I

Table I—Pumping Capacity at Greensburg Operations

Mine	Gal. Per Minute

## Old Workings at Cassidy, B. C., Flushed with Fine Rock

Hope to Prevent Spontaneous Combustion—Borehole  
Sunk Through Quicksand and Solid Rock—Stow-  
ing Material Carried Underground by Flume

BY JAMES B. TOUHEY

Resident Manager, Granby Consolidated Mining, Smelting &  
Power Co., Cassidy, B. C.

AT THE COAL mines of the Granby Consolidated Mining, Smelting & Power Co., some of the old workings are being flushed with broken rock to prevent spontaneous combustion. Support of surface and recovery of 100,000 tons of pillar coal by skipping and further flushing are expected to be the outcome of the experiment.

For many years mine workings have been hydraulically stowed in Europe. This method of surface support, however, has never found much favor in British Columbia, or, for that matter in any part of North America, probably because the workings have a life far shorter than those of Great Britain or Continental Europe.

When surface structures, such as railroads, towns and the various buildings necessary to coal-mine operation, are to be protected, it has been necessary to leave substantial pillars of coal to prevent subsidence of the surface. This is often inconvenient and at times expensive because of the great length of narrow work that must be driven in order to leave such supports. Within obvious limits also the nearer the coal lies to the surface, the larger must be the pillars that are left. If a river, creek or other stream crosses a property, it is always a hazardous operation to remove the pillar coal beneath it because rarely is the depth of gravel and glacial drift underlying such a stream definitely known. Of course, if a sufficient distance intervenes between the coal and the solid bed of the watercourse, no danger is to be anticipated from fractures extending upward to the water-bearing gravel.

At Cassidy, B. C., which is situated on the island of

creased pumping beginning 12 to 48 hours after, this period, depending on the amount of rainfall and condition of the soil.

An effort is made to do all pumping at hours of off-peak electric load. Pump station operators are instructed to this effect and in case an argument arises regarding the correctness of their reports, the chart of the main graphic demand meter for that mine is consulted. The pump motors are all of such size that the addition of their continuous loads to the fluctuating mine loads can be distinguished on the meter charts without difficulty. Only at rare intervals are pumps operated simultaneously with the peak day-load, these occurrences being caused by emergency or by the carelessness or misunderstanding of the operators.

Mine pumping appears to have received its due share of attention from the officials of the Keystone Coal and Coke Co. The new central pump station here described was built because the men of the company realized the necessity of having reliable drainage equipment that would meet emergencies.

Vancouver, the mines are entered from the surface by means of three slopes having an average pitch of 20 deg. The coal on Vancouver Island is quite liable to spontaneous combustion, and this forms one of the greatest dangers to be guarded against in mine operation.

When the mines at Cassidy were opened, advantage was taken of experience that had been gained at other operations in this regard, and a modified system of panel work was adopted, so that if a fire should start from spontaneous combustion or other cause in any particular panel or district, it could be quickly and effectively sealed without seriously interfering with the operation of the mine as a whole.

### VENTILATION AND STOWAGE REDUCE FIRE HAZARD

The mine was provided with ascensional ventilation so that all the old workings in each district could be ventilated by the return air from that district. Thus the returning air assisted in keeping to a minimum any heat that might otherwise be generated in the crushing of pillars.

It was finally decided as an extra precaution to stow the workings by hydraulic means. With this end in view, a slope 9 ft. wide by 7 ft. high was driven to within 63 ft. of daylight. It was planned to sink a small shaft from the surface to the face of this incline. This plan was abandoned, however, owing to the shaft encountering 11 ft. of quicksand. It was then decided to sink a borehole and case it with 6-in. steel pipe.

A suitable drill rig was accordingly erected, and a hammer weighing 400 lb. was used to drive the first length—10 ft. of 6-in. pipe—through the surface soil and gravel. The hollow drill rod standing in the middle of the pipe served as a guide for this hammer, which was raised by a small compressed-air hoist and allowed to fall by its own weight.

This device was manipulated as follows: The first length of pipe was put in position with a small framework about 6 ft. high holding it vertical. Water was next forced through the hollow drill rod by a 4x6-in. high-pressure pump. The rod inside the pipe with the hammer weight straddling it is shown in Fig. 1. A 1½-in. hemp rope, attached to the hammer, was

passed three times around the small drum of a hoist. In this manner the hammer was lifted about 10 in., and allowed to fall by giving slack to the rope, the hoist meanwhile being operated continuously. The force of water in the hollow guide rod was 45 lb. per square inch. This was sufficient to force the sand and gravel to the top of the pipe as it was driven downward. This method of sinking the casing was continued by attaching additional lengths of pipe until a depth of 43 ft. had been attained. Here, hardpan was encountered.

It became necessary at this point to drill the remain-

**Figs. 1 and 2—Driving Casing and Reaming Hole**

Through the surface drift the casing was driven by forcing water under pressure through the hollow drill steel and raising and dropping a heavy weight on the top of the casing as shown in Fig. 1. Fig. 2 shows how the drill hole was enlarged to the proper size to receive the casing. The hole was reamed by a "wing" bit attached to the side of the drill rod, the drill itself serving as a pilot and guide.

ing 20 ft. through hard shale. The hole must, of course, be of such size as to allow the casing to follow it down to the coal. An ordinary drill bit was made  $2\frac{1}{2}$  in. in diameter. Four  $\frac{1}{8}$ -in. holes were drilled from the flanks of the cutting edge to the hollow center. Through these streams of water were forced continually to keep the borings coming to the surface. A  $2\frac{1}{2}$ -in. hole was thus drilled to the coal and was then reamed out by an extra cutting bit fastened to the drill rod 1 ft. above the regular bit, this arrangement being shown in Fig. 2. The reaming bit extended  $3\frac{1}{2}$  in. on one side only from the center of the drill rod. It was lifted and dropped in the same manner as the hammer, thus cutting the sides of the original hole out to 7 in. in diameter, the smaller bit serving as a guide.

Inasmuch as the reaming bit extended to one side of the rod only, it allowed the two bits to be hoisted out of or lowered into the hole as required, passing up through the 6-in. pipe, the lower end of which was raised a sufficient distance above the bottom of the reamed portion of the hole to allow the  $2\frac{1}{2}$ -in. advance bit, which now served as a guide, to swing over out of a concentric position. In lowering this device back into the hole, the advance or guide bit, when it encountered the slant surface made by the reamer, would slide over into the smaller hole where it again acted as a guide, so that chopping with the reamer might be continued.

#### WATER TRANSPORTS WASHERY REFUSE TO BOREHOLE

The casing was pulled up 15 in. above the hardpan and allowed to remain in this position until the hole was reamed to the bottom. It was then lowered to the coal and secured in position on the surface. A small wooden hopper with a capacity of about two tons was next built above the borehole, the casing forming its vertex.

A flume was next constructed to carry the washery refuse to this hopper. This was made of 2x12-in. planks and lined on the bottom with  $\frac{1}{8}$ -in. iron sheets. It had a grade of 1 in 30. About eight parts of water to each part of solids was found necessary to keep the refuse flowing in this flume. Three feet away from the hopper a short length of copper screen was inserted in the bottom of the flume, after the plank had been cut out. The perforations in this plate were  $\frac{1}{8} \times \frac{1}{2}$  in., and sufficient water was drained out by this screen to prevent an excessive quantity of water passing underground. The ratio of water to solids was now about 4:1, and the slope within the mine was sufficient to carry this mixture along without the aid of fluming except where the direction of flow of the stowage material was changed or where levels had to be crossed. At present this material is being deposited in an old slope 1,100 ft. from the borehole. From this a number of rooms had been worked where because of the excessive roof and side pressure and the close proximity to a creek, pillars could not be extracted.

When this portion of the mine has been flushed full it is the intention to extract these pillars by skipping them, that is by taking slices off the sides and then filling up again after each slice. It is also planned later on to install a small rock crusher above the hopper and to crush all rock coming from the mine, which amounts to about 125 tons per day. This crushed rock—which will be less than one inch in diameter—will drop into the hopper where it will mix with the water and solids coming from the washery. This will increase the quantity of solids passing into the mine to approximately 250 tons per 8-hr. shift.

The entire cost of labor entailed in this installation, including that for drilling, was about \$350. The quantity of pillar coal that will eventually be extracted as the process of hydraulic stowage proceeds, will be approximately 75,000 to 100,000 tons. The primary object sought in stowing in this mine is the prevention of mine fires arising from spontaneous combustion in crushed or shattered pillars. Stowage will, however, prevent any appreciable surface subsidence arising from pillar extraction, shorten the distance the ventilating current must travel and prevent possible accumulations of methane.

## Coal Balls—The "Finger Prints" That Identify Coal

In These Limestone Nodules Fossil Plants Unerringly Establish Age and Character of Each Seam of Coal Says Noé

BY F. L. CLARK  
McGregor, Iowa

A SEARCH for "coal balls" in the coal measures of Illinois, Indiana, Kentucky and Iowa has been a particular feature of a geologic survey advanced during the past summer by Dr. Adolph Noé, paleobotanist at the University of Chicago. The first of these to be discovered in America was found in Illinois in 1922 and since then Dr. Noé has been working to develop

been made in the coal beds of England, France and Germany for a long time. Thus Dr. Noé's investigation leads him to believe that coal balls probably are fairly common in Iowa, Kansas, Missouri, and Indiana, and presumably are present in the Pennsylvania coal fields. Some of these nodules were recently found in Texas and forwarded to Dr. Noé for examination.

Of the commercial value of the discovery of coal balls of American coal-field origin and their examination Dr. Noé says, "Fossil plants, which are found in the coal fields are, as a rule, connected with definite seams, each seam having a flora of its own. Therefore, whenever fossil plants are discovered in or about a coal bed, that bed can be identified by them. It is of the utmost importance that this should be done because the commercial value of coal differs from bed to bed and the prospector must know what measure he has before him.

Figs. 1, 2 and 3—Plant Remains Found in and in Close Proximity to Coal Beds

Heretofore it has been believed that the coal beds were formed from dense masses or bogs of ferns, club mosses, horsetails and other plants of a low order of vegetation. Note, however, the shamrock-like plant appearing in Fig. 3. This shows a distinctly higher order of plant development than the other two, indicating formation of coal in a different era.

a fund of knowledge about "coal balls" and their value to the coal industry.

"Coal balls" are rounded limestone nodules found in the coal bed. They contain perfectly preserved fossil plants of the kind that formed coal beds of the world during the carboniferous age. These peculiar formations have been found in European coal measures since 1836 and have given to science an accurate knowledge of the plants that lived on the earth during the period when the coal beds were being laid down.

When one of these coal balls found by Dr. Noé, near Harrisburg, Ill., in 1922, was examined microscopically the discovery was made that it contained the stem of a flowering plant similar to a present-day cornstalk. This discovery appears to relegate to the discard previously conceived theories of the age of the earth, as the coal balls of Europe had revealed only club mosses, horsetails and other of the lowest forms of plant life. The discovery in a coal ball of a flowering plant, a type of life that science had believed had been developed only millions of years after the coal beds were formed, indicates that the world is a few hundred million years more or less older than it had previously been believed to be.

Whether or not Dr. Noé will find duplicates of his "King Tut of plants," as it might be called, in the explorations which he proposes to make during coming seasons in the Midwest coal fields, may be a matter of doubt. In any case such a discovery would be of interest to science if not to coal operators.

The significance of this work to the coal producer lies in the fact that the coal beds of America may now be given the same careful search for "coal balls" that has

In many instances he does not possess this information. Coal mines have been worked for years without the operators really knowing what beds they had or they gave the beds only local names without reference to the distribution of a particular coal.

"Coal balls contain materials which, when examined

Fig. 4—What Is the Story Here?

This particular coal forming plant is of an unusual type and might indicate the formation of the coal in a time varying from that usually assigned. The jointed stem of the plant, evidently is endogenous—the species which develops from the core instead of by adding outer layers—and resembles a corn stalk.

Fig. 5—Coal Ball Split Through Its Center

Here can be seen the beautifully preserved fossil plants inside. Each coal bed has its characteristic flora. Consequently the fossil plants in a coal deposit serve as a means of identification. Coal measures thus may be recognized as unerringly by their fossils as criminals are by their finger prints.

with a microscope can be identified with great accuracy. The fossil plants that appear in a coal bed are mere impressions in the shale or sandstone but if well preserved they can be closely identified. These are the occasions when fossil plants play a practical role. It can be easily imagined that in prospecting for coal beds in regions which have not been defined or drilled, special attention must be given to those fossils which are invariably found associated with that particular coal."

The accompanying illustrations are made from photographs of fossil plants found in the No. 2 coal bed of Illinois. This particular measure is of high commercial importance because of its chemical qualities. It produces an excellent fuel for the steel industry.

### Spitzbergen, the New Coal Bin of Norway

THE hitherto little known group of Spitzbergen islands off the coast of Norway have suddenly assumed great commercial prominence due to the discovery by Dr. Adolf Hoel, of the University of Christiania, of the great extent of its coal deposits.

According to the survey just completed there are in this area over 8,000,000,000 tons of high-grade coal of which quantity 1,500,000,000 tons are of Carbonaceous formation, 1,500,000,000 tons are of Calcareous formation, the remainder of the deposit being of the Tertiary formation. Though all this coal does not belong to Norway the large quantity that does belong places her in a promising position. Considering only that part of the tonnage held by the largest operating company and entirely overlooking other Norwegian companies and the possibilities of further extensions of the known fields she possesses an average of 600 tons of coal per inhabitant.

Many Norwegian companies are operating in these fields and others are being formed for the purpose. It is understood that there will be no objection to the introduction of outside capital, provided that the companies are organized under the Norwegian laws and administered in Norway. A few years ago a group of

Hollanders negotiated for the development of certain of these areas in this manner. Last year Norwegian and other companies employed 1,192 men in working their holdings, and this year a larger number of workers will be engaged. Most of the miners are Norwegians, the government doing all in its power to make the men and their families content by establishing hospitals, schools, churches and libraries. The workmen are given six months' contracts and are housed in modern homes.

Last year this little group of islands exported 340,000 tons of coal as against 19,000 tons in 1916. Of this quantity Norwegian-owned mines were responsible for 229,596 tons and foreign-owned mines for 113,346 tons. Up to date about \$20,000,000 have been expended in the development of these mines, but the next year will probably witness a material increase in the capital invested in this work.

At present the largest operating company is Norwegian, its holdings containing approximately 1,500,000,000 tons of coal. This organization, known as Store Norske Spitzbergen Kulkompani, is both progressive and aggressive and is in the market for modern coal-mining machinery of all classes. Plans have been under way for some time to open two new mines at Green Harbor, which it is understood will have an annual output of 300,000 tons each.

### Can Run Mine Cars on Railroad Track

BY C. E. REYNOLDS

Superintendent, Allegheny-Pittsburgh Coal Co.  
Logans Ferry, Pa.

In the supply yard at the Springdale mine of the Allegheny-Pittsburgh Coal Co., Logans Ferry, Pa., heavy oak planks are laid in and around a 70-deg. crossover of mine and railroad tracks, thus forming the platform shown in the accompanying illustration. The

Platform Flush with the Rails

Any piece of heavy mine equipment may be unloaded from the railroad car, moved to this platform and transferred with ease to the mine track.

railroad track is provided with a third rail at mine-track gage, which extends from the secondary tippie to the crossover.

Mine cars, locomotives and cutting machines are lifted from open railroad cars by means of a block hung from the tippie structure. They are then lowered to the rails laid at mine gage. Next they are moved from the unloading point to the crossover platform. This is flush with the top of the rails and facilitates slueing the car during its transfer from one track to the other.

## News Of the Industry

### Coal Trade Fails to Realize Importance Of Oil Competition

Overproduction of Petroleum Presents Problem Similar to That Facing Coal Industry—Leadership in Power Output Claimed by Oil Producers Questioned, but Margin Is Close

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

To bring to all branches of the coal trade a keen realization of the proportions of oil competition is one of the crying needs of the day, in the opinion of those deeply interested in the welfare of this industry. The conditions which brought about the production of 730,000,000 barrels of petroleum in 1923 are thoroughly unsatisfactory to the oil industry. It represented a glut of overproduction on a scale never before known.

Coal mines can be shut down, but the only way oil production can be checked is through an agreement among all producers in an entire field. This cannot be done legally under the interpretation which the courts are placing on the anti-trust statutes. This overproduction of oil, which is flooding the market, bursting storage facilities and building up unprecedented stocks of surplus crude and gasoline, does not spell prosperity to the oil industry. It means ruinously low prices—prices so low that the industry is forced to displace coal in order to realize anything from its surplus. Not only is coal suffering from the same trouble as oil but coal has an additional interest in some agreement that will halt overproduction in that surplus oil must be sold in displacing an enormous amount of coal.

#### Standard Oil Co. Boasts

Those who are studying the effect of oil competition on coal are convinced that the industry itself lacks a clear realization of the extent of the inroads being made. The Standard Oil Co. just at this time is boasting in newspaper advertising that oil now is the chief source of power in the United States. The inference is that it definitely has displaced coal from the head of the list. An analysis of the situation indicates that the claim of the Standard Oil Co. is not justified but it also shows that while coal probably still is in first place the margin between it and oil is a very narrow one. By narrowing the comparison to power—excluding heat—it is necessary to include gasoline as well as fuel oil in the calculation.

The 730,000,000 barrels of petroleum produced last year is equivalent to

200,000,000 tons of coal. The 1923 output of anthracite and bituminous coal combined was 657,000,000 tons, so that at first glance the ratio of coal to oil still would seem to be three and one-half to one even on a B.t.u. basis. Out of the 657,000,000 tons of coal, however, a considerable deduction must be made since a part of it is not used in power production. In round numbers these deductions would be: Anthracite, 70,000,000 net tons; bituminous coal used as domestic fuel, 60,000,000 tons; coal for coke, 80,000,000 tons; exports and bunker, 30,000,000 tons; heating requirements of the industries, including cement and brick manufacture, metallurgical and other uses, as well as that necessary to keep factories warm, 50,000,000 tons; gas works, 6,000,000 tons. This leaves a balance used for power of not more than 360,000,000 tons.

#### Oil Has High Thermal Efficiency

This would seem to indicate that coal still had a lead of almost two to one over oil, even when power uses only are considered. However, consideration must be given to the fact that more power is squeezed out of oil than is produced from coal. While it is true that the ordinary gasoline engine falls far short of the 35 per cent thermal efficiency which it gives theoretically, in actual performance it does much better than the ordinary steam plant burning coal and makes a locomotive look sick in comparison. The gasoline engine delivers at least 15 per cent over-all thermal efficiency, whereas the locomotive, considering standby losses, has less than 5 per cent efficiency. When allowance is made for the superior efficiency of gas engines over steam engines in getting power units out of fuel units considerable of the lead of coal is overcome.

Since no accurate calculations have been made of the average efficiency of steam plants, only approximations can be used. In all probability an assumption of 7 per cent of the average thermal efficiency of the coal-burning power producing equipment is high. A corresponding assumption of 10 per cent for the petroleum-using power producing equipment (including gasoline en-

### "Back to Coal" Movement Still On

A recent report of the Young Men's Christian Association of Boston in reference to the heating of its building contains this interesting statement:

"We are glad to call attention to the fact that we are now burning coal in the heating plant at a very distinct reduction in the heating price at the present time over oil. The decision to change from oil to coal-burning was made after careful study of the situation, in which we were greatly helped by the engineering school. If the present prices prevail, we should show a saving of several thousand dollars during the year by using coal in our heating plant."

gines) probably is low. The coal industry then will be willing to accept the following equation:

$$360,000,000 \times 7\% = 25,200,000$$

$$200,000,000 \times 10\% = 20,000,000$$

Now the comparison has shrunk to proportions of 25,200,000 for coal to 20,000,000 for oil. Under the most favorable conditions this is all of the lead which coal has as a power producer. The petroleum industry, of course, will insist that steam efficiency is less than 7 per cent and would raise the 10 per cent assumed for petroleum products.

While this calculation is rough it serves to point out the extraordinary inroads which oil has made in the field of power production. The coal-burning equipment includes most of the 65,000,000 hp. represented by steam locomotives. It includes most of the 20,000,000 hp. of the central stations and most of the 30,000,000 hp. of prime movers in industry and most of the 6,000,000 hp. employed in mines. This represents some 120,000,000 hp., but the power plants of automotive vehicles alone greatly exceeds that total. There are 16,000,000 motor vehicles in the country with an average actual horsepower which is certainly not less than twenty-five. On that basis the installed capacity would be 400,000,000 hp., more than three times the figure for coal-burning equipment.

The coal industry still is strongly entrenched in the heating field, but even there the small oil burner is winning favor. Any frank appraisal of the situation leads to the conclusion that coal must join hands with oil in a determined effort to eliminate the wastes of overproduction.

## 186 Miners Lose Lives in September Mine Accidents; Nine Months' Total 1,821

Accidents at coal mines in the United States in September, 1924, resulted in the death of 186 men, according to reports furnished by State mine inspectors to the U. S. Bureau of Mines. The number of fatalities reported includes 39 deaths in an explosion at Sublet, Wyo., on Sept. 16 and 5 deaths in an explosion at Rains, Utah, on Sept. 21. As the output of coal in September was 48,624,000 tons, the fatality rate for the month was 3.83 per million tons mined, as compared with 3.97 in the previous month and 2.94 for September last year, during which month no large disasters occurred, and an average rate of 3.60 for September during the 10-year period 1914-1923. For bituminous mines alone the reports showed 157 lives lost and a fatality rate of 3.83 per million tons, as compared with a rate of 2.70 for September last year and a ten-year average rate for September of 3.30. For anthracite mines alone, the number of fatalities in September was 29 and the fatality rate was 3.82, as compared with 6.86 for September last year and a ten-year average rate for September of 5.57.

Reports covering the first nine months of 1924 show a total of 1,821 lives lost in accidents at coal mines, as compared with 1,942 in the corresponding months last year. The fatality rate for 1924 to the end of September stands at 4.51 per million tons, as compared with 3.89 for the same period last year. For bituminous mines alone the average

### Mule 20 Years "Below"

Frequent mention has been made of the faithful old mine mule which has been kept underground for a term of years, then retired to old age by the mining company. The Penwell Coal Mining Co., of Pana, Ill., has just removed a mule to the surface which has been underground for more than twenty years. He has been retired to pasture on an old-age pension. As might be expected, he was blinded when he first saw the light of day, but his sight gradually returned.

rate in 1924 for nine months was 4.34, as against 3.59 in 1923. For anthracite mines alone the 9-month average rate was 5.34 as compared with 5.68.

The two explosions in September brought the total number of "major" disasters in 1924 to 9 with a loss of 452 lives, as compared with 7 similar disasters and 254 lives lost during the first nine months of 1923. The fatality rate per million tons based exclusively on the number of lives lost in accidents killing five or more men during the first three-quarters of 1924 was 1.12 as compared with 0.51 in 1923.

Comparing the causes of the fatal accidents in 1924 to the end of September with those for the same period in 1923, the record shows that explosions of gas and coal-dust continue to be the only class of accidents with increased fatality rates.

## Italy Imports More Coal from United States and Germany

Italy's imports of coal and coke during the first six months of the current year, according to the official figures given out by the Ministry of Finance, amounted to 3,666,690 tons against 3,818,962 in the corresponding period of 1923 and 3,065,491 in 1922, says Assistant Trade Commissioner J. A. Palmer, Rome, in a report to the U. S. Department of Commerce. In addition, 1,474,246 tons was received on account of reparations from Germany, compared with 950,628 tons in 1923. These figures, although official, do not coincide with those issued by the Reparations Commission under date of July 21, which placed the quantity of coal and coke shipped to Italy during the first half of 1924 on reparation account at "about two million tons."

Imports of American coal continue to grow, averaging about 47,000 tons per month during the first six months of this year against an average of only 20,000 tons during the same period last year. Germany's shipments of non-reparation coal also shows a substantial increase over last year, being in excess of arrivals from the United States whereas in the past, they were smaller. Shipments from France continue to decline.

Imports of British coal and coke, which, as a result of the reduction in reparation deliveries, were unusually high during the first six months of 1923 (3,398,385 tons), fell back to 2,831,543 tons in 1924, or about the same level as in 1922.

## Industrial Board Probes Trade-Association Work

The policy of the government toward co-operation and combination in private business enterprise, as expressed in the anti-trust laws, judicial practice, and the activities of the Federal Trade Commission, present difficulties and unsolved problems of the greatest public importance, says the National Industrial Conference Board in a statement just issued.

A lack of a clear and definite expression of public policy toward certain forms of business activity which have grown up out of changing economic conditions jeopardizes business and industrial development, the board says, and raises questions of vast importance to the public and the business community.

In this connection it was made known that the National Industrial Conference Board has been engaged for over a year in an intensive study of the development and present status of public policy toward private business enterprise, with special reference to the application of the anti-trust laws. This study, it was announced, covers the legal and economic aspects of the development and regulation of industrial combinations and the control of various forms of business co-operation and trade practices, the financial and economic aspects of business combinations, the relation of anti-trust laws to labor and the bearing of industrial combinations upon foreign trade and international affairs.

The purpose of the whole investigation, states the board, is to clarify for the public and the business community the present situation with respect to governmental policy so as to provide a sounder and more scientific basis for discussion of the vital issues which have arisen out of that situation. The investigation is being carried out by the research staff of the board in co-operation with a group of legal and economic authorities of national eminence in this field, and a large body of industrial and business leaders.

## Coal Stock Excites Utah

In Utah vigilance committees of the Cache County Farm Bureau and the Logan City Chamber of Commerce are waging a vigorous war on coal stock salesmen. It is asserted there are salesmen for four different coal companies in the county selling stock that is not a desirable investment. A widow is said to have been persuaded to part with \$2,000 of insurance money for some of it.

Those behind the anti-coal-stock-salesman movement are telling the people that too much coal is being produced already and that buying stock keeps more useless mines open, reducing working time and thus is responsible for keeping up the price. "Can't you see the handwriting on the wall?" says one message. "Let the big coal operators who have their money invested and are prepared to supply the coal put up the money. Don't sink your hard earned money in a coal or other mining scheme. It will never pay." It is understood that the attack is on the several mutual companies that are springing up.

The board's announcement says that since the whole issue of public policy has been raised recently in connection with the effort of the Secretary of Commerce and the Attorney General to define what trade associations may or may not do, the first report resulting from the board's investigations is a comprehensive survey and analysis of "Trade Associations and Their Activities." This report, to be issued soon, analyzes the development of trade associations and the legal status and economic importance of their activities, and will focus national attention on the place of trade associations in our industrial economic structure.

## Pennsylvania Abandons Plan To Lease N. & W.

After negotiations extending over nearly the last year, announcement was made Oct. 28 by the Norfolk & Western Ry. and the Pennsylvania R.R. that plans for a long-term lease of the Norfolk & Western property by the Pennsylvania had been abandoned because a financial basis could not be agreed upon.

The statement, issued by A. C. Needles, president of the Norfolk & Western, said: "The Pennsylvania Railroad Co. has been unable to make a proposition for a long term lease of the Norfolk & Western property on a financial basis which in the opinion of the Norfolk & Western directors would be satisfactory to its stockholders, and all negotiations for such lease have therefore been concluded. The conclusion of these negotiations will not affect the friendly relations existing for a long time between the two companies and which have been to their mutual benefit and to the advantage of the territories served by both."

## Lewis Sure of Re-election

The re-election of John L. Lewis as international president of the United Mine Workers is being forecast in Indianapolis. Nominations for international officers have been closed, and while ballots have not been prepared officially and it is not known exactly who, if anyone, will oppose Mr. Lewis for the presidency, it was said at international headquarters that Mr. Lewis seems to have almost a clear field. Likewise there is no formidable opposition to the re-election of Philip Murray as international vice-president, and William Green as international secretary-treasurer. In former years Mr. Lewis has met with formidable opposition when radicals led by Alex Howat, then president of the Kansas district, and Frank Farrington, president of the Illinois district, sought to capture control of the international organization.

## Campaign for Clean Coal Meeting with Success, Ohio Engineers Report

The report of the committee on the evaluation of coal, appointed at the January meeting, was the main subject at the sixth annual meeting of the Southern Ohio Pig Iron & Coke Association, held at Columbus, Oct. 17 and 18, jointly with the Ohio Section of the American Institute of Mining & Metallurgical Engineers. W. W. Stevenson, Semet-Solvay Co., Detroit, chairman of the coal evaluation committee, reviewed the committee's work, stating that the evaluation of coal was such a large subject that the committee felt that for the present at least it would be well for it to consider only the evaluation of coal for blast-furnace use.

The committee took the analysis of coke agreed upon by the Southern Ohio Pig Iron & Coke Association as a basis for discussion, and a recommendation was made that the base coal to be used for byproduct coking purposes should have approximately 6.5 per cent of ash on a dry basis and a volatile matter content such that 1.45 tons of coal would be required for one ton of coke. The tentative recommendation also was made that moisture should not be over 3 per cent, and sulphur no greater than 0.75 per cent, with a penalty for sulphur above 1 per cent. The recommendations of the committee were made after full discussion, aided by charts showing experiments conducted by L. R. Forest, Semet-Solvay Co., Syracuse, which showed the advance in the cost of producing pig iron from high-ash coal.

### Try to Evolve Base Coal Analysis

Following discussion of the committee report it was recommended that the committee continue its deliberations, taking in also the evaluation of coal for gas-producer and steam use and endeavor to arrive at a base coal analysis similar to that used in the iron-ore trade, and above which a premium would be paid for coal, with a penalty for coal below the base grade.

The clean-coal campaign inaugurated by the association two years ago, President Sweetser said in his address, was having wonderful success. He declared that since the matter had been brought to their attention the coal operators were determined to set their house in order without interference from outside sources, and cited the change in advertising methods of many companies, in which clean coal was stressed. Whereas two years ago it was almost impossible to get clean coal, today coal can be bought on a guaranteed basis. The campaign was an educational one, and it is getting down to the miners themselves, as in a recent agreement signed in an Ohio district the miners agreed to take every means in their power to mine clean coal.

The question of sampling coal was taken up in a report by C. B. Murray, secretary of the Ohio Section of the American Institute of Mining & Metallurgical Engineers, in which he cited a number of methods of sampling, and recommended that the proper place for sampling was at the mines. Coal anal-

**John H. Jones**

President of the Bertha-Consumers Co. and well known as a pioneer in the creation of the modern mining town.

ysis was discussed by Prof. D. J. Demorest, Ohio State University, who said that the only inspection necessary in cases where output of certain mines is purchased is for ash and sulphur. When buying from the jobber, all tests must be made, and in the case of coal for gas-producer use a check of the B.t.u.'s also was necessary.

A discussion of the methods of sampling and inspection followed a report by G. W. Coughlin, American Rolling Mill Co., Ashland, Ky., in which he described the value of the visual inspection carried on by his company at its mines. The main reason for this inspection is to check up the mines. The company has set up a quality standard for each section of mines. A complete visual inspection checked by a 20 per cent analysis made a complete but not costly standard. Referring to the value of the inspection department, Mr. Coughlin said that for a six months' period the ash content of coal mined in the various sections where inspectors were employed had dropped approximately 50 per cent.

Discussion of the report revolved about the establishment of control laboratories at coal mines, from which a quick report could be obtained as to the analysis of coal being mined. It was felt that if it were possible to have control laboratories established, it would be a very profitable investment for the producer. Prof. H. E. Nold, of the Mining Department of Ohio State University, stated that with such a laboratory the producer would be in a position to know just what kind of a contract to accept, thus eliminating the danger of having coal rejected on reaching destination.

Further discussion on the question of rating of mines, grading of mines, grading of coal, education of miners, producers and consumers, and of waste took place before the meeting adjourned, but no action was taken on any definite recommendation, it being felt that the association should make only tentative recommendations until the question of evaluating coal be more thoroughly discussed.

## Efforts to Merge More Mines Continue in Kentucky

Large expansive talk about a ten million dollar merger of western Kentucky mines floods the region these days, due mainly to the activities of a scattered group of financial men such as L. H. McHenry, a surety bond holder agent of Louisville, Ky.; P. B. VerPlanck, George E. Hutchinson, Joseph A. Howorker and R. S. Morriss, of Chicago; R. J. Jones, of Columbus, Ohio, and Edward C. Larkin, of Dayton, Ohio. But up to date no merger has progressed beyond the stage of engineering appraisals and a general feeling out of the situation by banking groups.

Seven mines are under option that is reported to expire Nov. 4. The seven are all in the Muhlenberg field, near Central City, Ky., and are all strike bound at the present time. It is reported that the deal involves two mines of the W. G. Duncan Coal Co., at Graham and Luzerne; the mine of the Wickliffe Coal Co. at Browder; two mines of the Greenville Coal Co., at Powderly and Martlewick; a mine of the Pacific Coal Co. at Mercer and a mine of the Nelson Creek Coal Co. at Nelson Creek.

Most of these properties have long been known to be for sale because of the troublous conditions in Muhlenberg County, but nobody has been able to offer enough to buy them and those who have the money to buy at a reasonable price have been afraid of the whole thing because of the strike which has kept the whole of the county tied up since last spring. However, there is a chance of the union strength of the county dissolving soon. Already a half dozen small mines in the county are working on an open-shop basis at the 1917 scale and it looks as if the rest of the county might slip out of the union strangle hold within a few weeks. This may open the way for a mine merger.

## Western Canadians Work Despite Close Vote

With reference to the recent settlement of the coal strike in District 18, United Mine Workers, it is interesting to note that there were majorities against a settlement in most of the coal mining centers of the Province of Alberta. British Columbia, however, was so overwhelmingly in favor of accepting the recommendations of the miners' representatives that the scale was decisively turned in favor of returning to work. The vote by districts is given unofficially as follows with "yea" vote given first: Drumheller, 527 to 1,105; Lethbridge, 220 to 235; Fernie, B. C., 495 to 63; Michel, B. C., 195 to 115; Coleman, 425 to 113; Edmonton, 1 to 39.

During the past week, however, reports indicate that the atmosphere is clear in all the coal fields both of eastern British Columbia and Alberta. The miners have accepted the verdict of the majority, taken up their tools, and returned to work on the terms of the agreement recommended to them. Production both in British Columbia and in Alberta from this date may be expected to reach substantial tonnages.

## Midwestern Engineers Visit Coal Mines of South Illinois Field

The annual autumn meeting of the St. Louis section of the American Institute of Mining and Metallurgical Engineers terminated at Duquoin, Ill., Sunday afternoon Oct. 19 after two days spent inspecting coal properties of southern Illinois. More than 100 men, many of them prominent in the mining of Illinois, Missouri, Oklahoma, Kansas, Indiana, Kentucky and Tennessee, attended. The local committee, under the chairmanship of Dr. L. E. Young, of St. Louis, general manager of the Union Colliery Co., arranged the program.

The visitors assembled at 8 a.m. Saturday at the St. Louis end of the Free Bridge, where cars awaited them. Their route was over the state hard road to Duquoin, a short stop being made at the new strip mine of the Gayle Coal Co., just north of Duquoin. This pit is one of the largest in Illinois. At Duquoin the party had luncheon at the St. Nicholas Hotel and spent the afternoon inspecting the large Kathleen mine at Dowell, owned by the Union Colliery Co., and the new strip mine of the Black Servant Coal Co., at Elkhaville. Returning, the visitors enjoyed an informal dinner at the St. Nicholas Hotel.

At 8 p.m. Saturday the men assembled in the dining room of the hotel, where for two hours they listened to a number of informal talks. J. D. Robertson, of St. Louis, well known mining engineer, presided over the meeting, and Walter E. McCourt of the Washington University of St. Louis, served as secretary.

### Tells Early Mining History

The first speaker was Arthur Hatcher, of St. Louis, who spoke at length on the geology of the mining district. James Forester, of Duquoin, superintendent of the Paradise Coal Co., told of the early mining history of southern Illinois. He was connected with the Halliday mining interests when they operated the old Hallidayboro mine, then one of the largest in the state. Prof. H. E. Culver, of Urbana, Ill., assistant state geologist for Illinois, in an interesting address dwelt upon the geology of the Duquoin anticline.

Charles F. Spencer of Pittsburg, Kan., spoke briefly of the mining conditions in that state. He is one of the pioneers in the strip mining industry in Kansas. "Doc" Shelton, of Marion, Ohio, a representative of the Marion Steam Shovel Co., enlightened the engineers on the mechanical principles of steam shovels now in general use in strip mines. Fred L. Shimer, division manager for the Central Illinois Public Service Co., spoke at length on the power situation of the southern Illinois coal fields. His company supplies seventy-two coal mines in the district with power and is now building a power plant at Grand Tower, Ill., on the Mississippi River.

Eugene McAuliffe, president of the Union Pacific Coal Co., with headquarters in Omaha, Neb., and former

## Will West Kentucky Ruin Unionism?

With the strike in Muhlenberg County, western Kentucky, crumbling, now that six mines there are operating open shop on the 1917 scale, another solemn warning, following that of the resigning district president, Lonnie Jackson, has been uttered by County Attorney W. O. Smith, former district president of the miners. Smith says in a public statement that if the union does not make a deal with the operators of the district at a reduced wage, non-unionism is going to spread to a point where all the coal the country needs can be produced by non-union mines and that therefore the United Mine Workers will crumble. The organization, by refusing to modify the Jacksonville agreement, is cutting its own throat, he says. Wise observers of the region predict that the whole of western Kentucky will be operating either non-union or open shop before Christmas.

president of the Union Colliery Co., talked about mining conditions in the West, particularly in the State of Wyoming, where most of his company's property is located. John Garcia, of Chicago, a member of the firm of Allen & Garcia, gave an interesting résumé of present mining conditions. J. E. Jones, of the Old Ben Coal Corporation, told the assembled guests how his company has successfully employed rock dust in combating explosions.

Sunday morning the party left in automobiles for a 75-mile trip through the principal coal mining towns of Franklin and Williamson counties, including an inspection trip underground in the new monster Orient No. 2 mine of the Chicago, Wilmington & Franklin Coal Co., near West Frankfort. The men returned to Duquoin at 2 p.m., when the party dispersed.

Figures on the amount of coal consumed by certain industries now being made public by the Bureau of the Census as the returns from the 1923 census of manufacturers are becoming available show the following: Malleable iron castings, 891,981 tons; mucilage, paste and other adhesives, 11,187 tons; bookbinding and blank book making, 22,428 tons; artificial flowers, 3,221 tons; jewelry and instrument cases, 4,398 tons; soda water apparatus, 17,368 tons; window shades and fixtures, 58,450 tons; billiard and pool tables, bowling alleys and accessories, 14,407 tons; sand and emery paper and cloth, 31,110 tons; dressed furs, 60,895 tons; chewing gum, 16,215 tons; leather gloves and mittens, 13,030 tons; lead pencils, 108,078 tons; artists' materials, 16,022 tons; wool scouring, 39,905 tons; silversmithing and silverware, 15,048 tons; malt, 88,969 tons; matches, 65,019 tons; cigars and cigarette holders and pipes, 4,376 tons; trunks, suitcases and bags, 21,431 tons; foundry supplies, 64,771 tons.

## Sproul Consolidation Of Hard-Coal Companies Practically Completed

Scranton, Pa., Oct. 31.—Following closely on the heels of the announcement by Frank W. Childs, New York financier, that a \$20,000,000 consolidation of anthracite properties was nearing completion, comes the authoritative statement the negotiations are being closed for another consolidation of a number of independent anthracite companies. William C. Sproul, former Governor of Pennsylvania, is interested in the latest merger.

The consolidation now announced centers around the Von Storch Collieries Co. and the Legitts Creek Anthracite Co., with four smaller companies also involved. Warren T. Acker, owner of the Von Storch company, admitted to interviewers that the deal would be closed within a few days, but declined to furnish other details.

For the last several months there has been talk of consolidating a number of local independent companies. Late in August former Governor Sproul visited the city, but denied his trip had anything to do with a proposed consolidation.

It was reported that Mr. Acker will be the president and general manager of the new company, although this could not be verified. Mr. Acker has had much experience in the coal business and is highly regarded among men actively associated with the industry.

The latest consolidation has no bearing on the one which Mr. Childs announced several days ago. Included in this proposed merger are the Kingston Coal Co. and the Jermyn Coal Co., together with several other smaller companies. Originally the consolidation being engineered by Mr. Childs included the Von Storch and Legitts Creek properties. The last named concern is owned by New York and Cleveland interests.

## Heavier Coal Traffic Likely On Ohio River Soon

Extensive plans are being made by coal producers to use the Ohio River for water-rail shipments. One large coal producing company already has made extensive use of the Ohio by sending its coal to Cincinnati by water and there transferring the cargoes to rail carriers. A material saving is made in the transportation charge. By the end of the year the task of providing locks and dams between Pittsburgh and Cincinnati will have been completed. This will provide a 9-ft. channel at ordinary low water. This is expected to stimulate greatly the water-rail coal business, as well as the shipment in that manner of steel and other commodities.

General Edgar Jadwin, Assistant Chief of Engineers, who just has returned from an inspection of the work on the Ohio below Louisville, reports that flood progress is being made in that sector, although there still is four years of work to be done before that portion of the project will be complete. The last of the plant that will be needed for the work is being assembled at Louisville.

## Practical Pointers For Electrical And Mechanical Men

### Motorman Cannot Operate Locomotive Unless Stationed Inside Cab\*

Device Eliminates Possibility That Operator May Start Motor and  
Let It Run Wild—Three Accidents of This Kind  
Had by One Company

By J. L. BOARDMAN  
Safety Engineer, Anaconda Copper Mining Co.  
Butte, Mont.

A MOTORMAN at one of the mines of the Anaconda Copper Mining Co., alighted from his locomotive and wishing to take up some slack in his trip proceeded to operate the controller from the ground. The locomotive got away from him, and in endeavoring to get aboard he was knocked down between cars and timbers, the trip running over and seriously injuring him. The locomotive continued to the "turn sheet" on which cars are switched at the shaft. There it became derailed. A shift foreman finding the locomotive

kind happened and the electrical engineers were asked to devise some method that would make such accidents impossible.

The device consists of a movable motorman's seat connected by a system of levers to the tripping mechanism of a standard overload circuit breaker mounted under the seat. The seat is connected also by a chain to a foot lever mounted on the floor. When the motorman's weight is on either the seat, or the foot lever, it allows the standard circuit breaker to be closed,

which is placed in the "pit" of the locomotive.

The seat A is hinged at the back and elevated in the front by the springs F. When pressure is applied to the seat it compresses the springs F and forces down the plunger K. This plunger operates the pin E through the lever D and

FIG. 2

#### Circuit Breaker Is Not Locked In

The pin E is forced against the tripping armature H and the circuit opened when the motorman steps out of the locomotive and releases the pressure on the seat or foot lever. The device does not prevent the circuit breaker from functioning when an overload is placed upon the locomotive.

releases the pressure on the overload circuit-breaker tripping device H allowing the circuit breaker to be closed by the reset lever C. Pressure on the seat can be provided by the motorman sitting upon it or by his pressing the treadle with the foot when standing.

If the motorman should leave the locomotive cab, thereby releasing the pressure on the seat, the pin E is forced in by the spring L and strikes against the tripping device H on a standard circuit breaker; this opens the circuit to the locomotive motors. The device does not prevent the standard overload circuit breakers from functioning on overload.

The movable seat can be adopted to electric operation of the circuit breaker by removing the levers connecting the seat to the breaker and installing an auxiliary contact or switch under the seat. This contact would control the opening or closing of the main circuit breaker and would have this advantage over mechanical operation that the breaker could be placed anywhere in the cab. The device was developed by J. M. Fine, superintendent of the electrical department and T. J. Little, foreman of the electrical shop of the company at Butte, Mont.

FIG. 1

#### Motorman Must Be on Seat or Have Foot on Lever

No, the motorman does not sit on the circuit breaker and hold it closed against an overload. When he sits on the seat or holds his foot on the lever the trigger is reset and the breaker can be closed. Just as soon as the motorman releases the trigger by getting off his seat and at the same time freeing the foot lever, the circuit breaker opens and power cannot be applied to the motors. This little safety feature was put on a locomotive so that the motors cannot be operated unless the motorman is in his cab and in proper position.

went back to the point where the trips were normally loaded and found the man lying by the cars.

Soon after this accident another of a similar nature occurred. Publicity was given to both mishaps, but a few days later a third accident of a like

but if this weight is removed the circuit breaker is automatically opened and cannot be closed until the seat or foot lever is again depressed. This cannot be done until the motorman is in the cab of the locomotive. Thus power cannot be applied to the motor if the motorman is not on the seat or does not have his foot on the treadle

\*Contribution to Mining Section, National Safety Council, Sept. 30.

## A Cost-Saving Method of Changing Wheels

The arrangement of a well-equipped locomotive barn is one of the main factors that keeps the repair bills to a minimum and is worthy of consideration. In most cases it has been my experience that when a locomotive is to be repaired, the necessary time that should be allowed is not available and

### Where Quick Changes Are Made

This pit is large enough to accommodate three sets of wheels and still leave ample room for the workmen. It is arranged so that the rails are taken from under the wheels. It is not necessary to raise the locomotive more than a few inches because the old set of wheels is dropped from the bottom and the new set raised from the floor of the pit.

consequently the job is rushed through in great haste and no accurate work has been performed, however, the motor has been put back in service. This is indeed a bad practice and can be largely avoided by the proper arrangement of the repair shop.

Take, for instance, the retrucking of

a locomotive. This can be done in a reasonably short space of time if the pit in the locomotive barn is properly designed. I have in mind a pit that I believe is worth mentioning. It will save time and money enough on a few jobs to pay for itself. This pit is so designed that a set of new trucks may be placed in it. The locomotive is then run over the pit and raised only enough to make up the difference in the size of the old wheels and the new ones. Then the locomotive is blocked up at each end of the frame with timbers long enough to reach across the pit. The rails are then removed from under the locomotive. A chain block is fastened to the center of the axle or preferably at each end close to the wheels and the weight taken on the chain blocks. All bolts and cap screws are loosened after the motor frame has been made secure. The set of wheels is then lowered into the pit where a new one is ready to be raised and bolted properly to the frame and motor. After this operation has been repeated for the other axle the rails are placed under the wheels. When the blocking has been removed from under the frame the locomotive is ready for oiling and going to work.

This kind of a pit may be slightly expensive to build but this is not to be compared with the savings which may be made in a few months. The entrance to the pit is at one side near the end.

J. H. BLAIR.

Moundsville, W. Va.

## Systematic Handling of Motor Parts Reduces Costs

System is a byword in the mechanical and electrical departments of the Island Creek Coal Co. of Holden, W. Va. It is applied in practice to every step incident to the handling and repairing of equipment, both at the mines and in the central repair shops. Needless delays are avoided and greater efficiency is procured from the repair men by adhering to approved methods.

When an armature, for instance, is removed for repairs from either a cutting machine or a locomotive, the repair men at the mines are instructed not to take time to remove the spur gear or the bearing housings from the shaft. A spare armature is provided with these parts in position to replace the defective one. Consequently, little time is spent in replacing an armature as all adjustments are made in the central shops and not at the mine.

Fig. 1 shows a number of armatures in various stages of dismantlement in

Fig. 1—Armatures in Various Stages of Repair

Repair men at the mines of the Island Creek Coal Co. do not remove the gears and bearing housings from an armature shaft when replacing armatures—there is plenty of time for that in the central repair shop where this picture was taken.

Fig. 2—Boxes for Armatures

These boxes are strongly built to protect the armatures they are intended to carry from injury caused by falls or jolts. Frequently rough handling may cause serious damage unless an armature is carefully crated.

the winding room of the central shops. When the tires or a gear on a locomotive axle is in need of repair the unit—wheels, axle and gear—is sent to the central shops, a spare unit having been made available in advance to replace the one removed.

L. D. Thompson, who has charge of this company's direct-current equipment, remarks, "The shop men are not rushed for time while overhauling and adjusting equipment parts. They can do their work with the care that ample time alone insures. On the other hand the mine repair men are pressed for time and the mine is temporarily crippled should the breakdown occur during the day shift. Therefore every feasible measure should be taken to shorten delays to equipment."

In order to guard against injury while motor parts are being handled to and from the shops and mines, the armatures are carried in strongly constructed boxes. The type of box for carrying a cutting-machine armature is shown in Fig. 2. It is built of wood and reinforced by two iron straps which are bent around the bottom and sides. The ends of these straps project above the sides of the box and through slots in a sheet iron cover. A hole is drilled in the ends of each strap for the reception of a cotter pin which holds the cover in place. Handles project from each end of the box to facilitate transportation. A somewhat similar box is provided for carrying locomotive armatures. These boxes have been known to roll and tumble down a hillside after being carelessly loaded on an incline car, without causing damage to the armature.

Each mine is provided with a spare armature for every type of machine and the central shops carry a few extras, not including those being repaired. When a defective armature is received at the central shops it is marked with a brass tag bearing the mine number for identification purposes.

# Production And the Market

## Continuance of Extremely Mild Weather Causes Coal Market to Mark Time

Continued mild weather is playing hob with the efforts of the coal industry to get under headway, the trade still being in the throes of the reaction that set in two weeks ago after a gradual but promising revival that lasted seven weeks. The usual pre-election hesitancy also has been a complicating symptom in the disorder that has the business temporarily in its grasp, buying for the time being having settled down in most instances to a strictly hand-to-mouth basis. The prolonged spell of unseasonably warm weather has not been entirely without consolation for the coal producer, however, for the drought in some sections has caused such a scarcity of water that hydro-electric power plants have been forced to use coal to keep going.

### Confident Undertone Prevails

With the election out of the way and general industry in the attitude of "business as usual," activity from now on promises to be a weather proposition pure and simple, the coal trade in the meantime hankering for the welcome whistle of wintry winds. A confident tone pervades general business conditions, reflected by record-breaking movement of freight on the railroads, increasing iron and steel orders, progress in the textile industry and improvement in the automobile trade.

**Coal Age** Index of spot prices of bituminous coal, after a long gradual upward climb, flopped badly last week, standing on Nov. 3 at 171, the corresponding price for which is \$2.07, a drop of 5c. from Oct. 27.

Activity at Hampton Roads underwent a slight reaction last week, dumpings of coal for all accounts during the seven-day period ended Oct. 30 totaling 363,818 net tons, compared with 384,268 tons the week before.

Coal movement up the lakes is in the wane, dumpings at Lake Erie ports during the week ended Nov. 2, according to the Ore & Coal Exchange, being as follows: For cargo, 688,548 net tons; for fuel, 38,272 tons, compared with 819,869 and 39,998 tons the previous week.

Bituminous coal output took a turn for the better during the week ended Oct. 25, when, according to the Geological Survey, 10,298,000 net tons was produced. This was a gain of 37,000 tons over the preceding week, according to revised figures, but was 255,000 tons less than the total for the week ended Oct. 11. Anthracite production, after three weeks of curtailment due to floods and other setbacks at the mines, came close to the capacity of the mines during the week ended Oct. 25, when 1,927,000 net tons was produced.

The anthracite market has suffered considerable of a setback from the weather after business had reached promising proportions, but the shrinkage in demand has been offset to a considerable extent by a falling off in production during the past week, brought about by the observance of Mitchell Day and a church holiday as well as by another local strike which kept about 10,000 miners idle for several days. Egg is moving more easily, some consumers taking it when unable to obtain stove, which leads in demand, as usual. Chestnut is holding up fairly well, but pea is rather slow. Trade in steam sizes is only fair. Independent prices are still firm, due to curtailed output rather than the volume of demand. The effects of the flood at the mines a few weeks ago are no longer much of a factor as far as production is concerned.

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Prays for Cold

Summer weather during late October may be hard on football teams but it is harder on coal men. The Midwest coal trade is gasping for breath, wiping the sweat out of its eyes and yearning for the whistle—of north winds. Domestic business is distinctly hard to handle, for householders are not buying heavily and mine tracks are filling with prepared sizes. There are no marked changes in circulars from such strong fields as southern Illinois, but western Kentucky is beginning to unload domestic sizes at 10 and 15c. off.

Of course small coal and steam sizes are in trouble. However, production in some of the Illinois and Indiana fields has been reduced, storage on the ground continues, and as a result not much drop in steam prices is noticeable except in the "off grade" fields. Everybody knows that cold weather is bound to come before long and the thing to do is hold on to slow sizes until then. Some mighty cheap coal has been traded from day to day on the Chicago market, where buyers are keen for all the advantages there are. Any good southern Illinois screenings that reach there without a buyer cannot hope to bring more than \$1.25. In the country, however, \$1.40 and \$1.50 are prevailing prices.

Eastern coal is not reaching the Midwest in any great volume because of this soft condition, but that which does

is selling a little under circular. Pocahontas, always popular in recent years around Chicago, has weakened a little.

The situation in the Carterville field continues fair for lump. Most mines are pretty well oversold. They are caught up on egg and are long on No. 1 nut, and the other sizes below that are a drag on the market. Mountains of screenings are stored on the ground near many of the mines in southern Illinois and it is only a question of a short time now until all storage capacity will be filled.

Railroad tonnage is fairly good and a considerable portion of this is coming from strip mines which seem to be working full time on account of the unusually pleasant weather and the fact that they can sell their coal in competition with western Kentucky non-union and also most anything else that they may have to compete with. In the Mt. Olive district warm weather has slumped off the domestic demand although there is still some moving and the steam sizes are pretty well taken care of on contract. In the Standard district it is still a day to day proposition with coal selling at cost or below. A car shortage has been developing recently. This was noticeable first on the L. & N. and is beginning to show up on points of the Pennsylvania, B. & O. and Illinois Central.

At St. Louis warm weather has eased up the domestic movement of coal. The trade is principally in the better grades. The movement of Standard and Mt. Olive will not reach its maximum until real cold weather sets in. Wagon-

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

Index	1924			1923
	Nov. 3	Oct. 27	Oct. 20	Nov. 5
Weighted average price	171	176	176	183
	\$2.07	\$2.12	\$2.12	\$2.21

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

load steam shows some improvement, while carload steam is lagging and somewhat slow and hard to find. There is very little country steam business and country domestic is slow. There is practically no anthracite demand, smokeless has dropped off and coke is unusually slow.

### Kentucky Keeps Busy

Due to the fact that Kentucky is producing coal on a non-union basis, it has been possible to market production quite freely and over a wider radius than usual, in spite of mild weather, but prices are weaker. The top of the eastern Kentucky quotations to retailers is around \$3.50 for best block and \$3.15 for western Kentucky. Good coal can be had as low as \$3 in either field. Mine run is \$1.50@1.75 in either field, and screenings are 60@70c. in western Kentucky and 85c. to around \$1.10 in eastern Kentucky.

Western Kentucky production has been increasing because several former unionized mines that were on strike have resumed operations. The lower end of the field is now running quite well, and it looks as if it will be only a short time before the Central City section of the field will show developments favoring production in a number of mines that have been down for nearly seven months.

### Northwest Trade Rather Dull

Trade remains dull at Duluth, the only feature being the demand for coal from North Dakota to take the place of cheap lignite used there last year. The good crop, and consequent financial affluence, together with the fact that lignite has not proved popular has tended to help bring back the market. Despite the lack of trade, prices are strong all along the line. There has been no change since last quoted. Coke is coming into popularity as it is priced at \$8.50.

Smokeless coals continue popular. The problem now is to find an outlet for soft coal screenings. The commercial buildings are being urged to use them, but of course they can do so only when they stoke by hand. The docks are trying to work up a trade in buckwheat for commercial heating, which trade was lost during the war when only bituminous was available.

Twenty-nine cargoes arrived at Duluth last week, of which only one was hard coal. Twelve are on the way from lower lake ports, of which one is hard coal. The drop off in anthracite seems to be in direct ratio to the demand, which is at low ebb.

The all-rail coal trade at the Twin Cities is shifting somewhat from southern Illinois to the other sections of that state and to Indiana, because of freight rates. Coal buyers seem to be adhering to all-rail coal, as far as they are buying at all, for there seems to have been little or no changing to dock since the extra 28c. on freight from southern Illinois became effective.

Railroad consumption in the Northwest has been materially increased in the last 60 days, for the grain movement has been the heaviest in a number of years. The roads have done excellent work in keeping traffic moving, but embargoes have been necessary to allow a cleanup twice.

The driest October in the history of Wisconsin and one of the warmest Octobers in the meteorological records has put the coal trade at Milwaukee in the doldrums. Wholesalers and retailers report no change in conditions from a week ago. But when colder weather does come—as it must—they expect a rush of orders, with increasing difficulty in getting supplies of certain grades because of the sold-up conditions at the mines, and also further trouble as to shipping equipment, as gondolas are short here.

Coal is coming to Milwaukee quite steadily by lake. The receipts during October, up to the 29th, were 104,640 tons of anthracite and 317,984 tons of bituminous coal, making the totals for the year thus far 677,294 tons of anthracite and 2,013,294 tons of bituminous coal. The receipts for the lake season of 1923, up to Oct. 29, inclusive, were 757,824 tons of anthracite and 2,522,101 tons of bituminous coal.

### Warmth Retards Western Business

In the Southwest a continuation of warm weather is causing the surplus of all grades to mount. Dealers have shown an unwillingness to lay in heavy supplies against the midwinter demand, so it is considered likely that with the arrival of winter it will be necessary to open more mines to take care of orders. Reports from Arkansas continue pessimistic. There several mines have been closed down entirely, due principally to the extreme difficulty of moving screenings. Kansas City prices are unchanged.

The market in Colorado is moving along fairly well with production continuing to show a slight increase each week. The extreme warm weather, however, is hard on domestic trade. Colorado mines worked on an average of thirty hours last week and, according to reports from the operators, only 23 per cent of the working time lost was attributed to "no market."

The car situation in Utah grows worse daily. Salt Lake City orders are cared for, but there is not enough of the right equipment for other markets. "We are getting very short of box cars and dump cars," said an official of one big wholesale company. This company has had to hold up an Idaho order for a week as a result of the car situation. The sugar beet harvest is largely responsible for the shortage. The market for Utah coal on the Pacific Coast is holding up better now than any other for Utah producers.

### Ohio Business Wilts in Warm Weather

Mild weather has caused the Cincinnati market to flop. Southeastern Kentucky operators are holding a stiff upper lip, but only a few ask \$3.25 for block and some sales of pretty good stuff are being made at \$2.75. West Virginia producers are settling around a \$3 asked price with sales down to \$2.50 for the low grades. Less and less interest is being displayed in egg and 2-in. as the end of the lake season nears. Run of mine is even stronger than a month ago. Good grades of gas are selling around \$1.50 with some Harlan and choicer grades up to \$1.75. Splints are around \$1.40 and in between grades are no lower than \$1.35. Slack has retreated a little on low grades with the better stuff holding firm. Smokeless prices show considerable divergence. River business has been hard hit by drought.

Dullness in steam business and hesitancy on the part of dealers to stock up further in the face of milder weather

sums up the situation at Columbus. Buying is limited to immediate wants and the trade is waiting. The domestic trade is wholly a weather proposition and until lower temperatures prevail there will not be a great deal doing.

The coal business at Cleveland is pretty much at a standstill so far as demand is concerned. Inquiries have been noticeably absent during the week, awaiting the outcome of the election. Should the result adversely affect business conditions, some softening in prices may be the outcome, but even if the result be favorable to business, prices are not likely to advance. Mild temperature has had a deterrent effect upon domestic demand and prices on smokeless fuels have receded about 50c. per ton. The steam buyer is content to continue a hand-to-mouth program.

### Demand Tapers Off at Pittsburgh

Demand seems to have decreased a little further at Pittsburgh in the past week, this being attributed to the influence of the election and mild weather. Production is holding at fully 50 per cent, the increased operation being largely in shipments by producers to regular customers. There has been a smaller increase in the turnover in the open market, in spot and prompt lots. Prices continue to show no change, the steadiness causing comment. On account of heavy production of domestic coal, slack has been pressing on the market, but prices hold fairly well.

Business is quiet all along the line at Buffalo; everybody is complaining. Some shippers say that their October trade will not show up as well as September did and but few find it to have been really better.

### New England Notes Favorable Undertone

In New England the undertone is favorable, but as yet there has been little change in prices. Buyers who postponed their purchases were finally obliged to enter the market, but aside from these there is no demand strong enough to support any pronounced upward swing.

At Hampton Roads smokeless coals are being held at \$4.45@ \$4.50 per gross ton f.o.b. vessel for No. 1 grade. Current receipts at the piers are being absorbed either on contract or on a spot basis close to the figures named. Mild request off-shore together with extra business coastwise has taken care of current restricted output, but in the judgment of many a material lift in prices would again paralyze what buying power there is.

On cars Boston, Providence and Portland there is a fair spot demand with prices averaging around \$5.50 per gross ton for coals on the Navy acceptable list. At Providence and Portland, especially at the latter port, a few factors are asking \$5.75, and for single car lots as high as \$5.90, but there is no great urgency on the part of buyers.

Shippers of quality coals in central Pennsylvania for delivery all rail are gradually picking up 30- to 60-day business at the minimum price basis established some months ago; \$2.25 for good "B" vein is about the level, but one has only to make a rough computation to see how far out of line such a figure is with Pocohontas and New River in the non-union area.

### Atlantic Markets Slow Down

Buying of soft coal is lower at New York. Consumers were believed to be holding off until after election day, but with that out of the way operators are wondering when the market will improve. Much depends on weather conditions. Consumers claim to have plenty of coal on hand and do not seem to be worrying over a possible car shortage or difficulty in getting coal when they want it. Prices continue to show a wide range, but are holding to a steady level despite

heavy production and the opening of additional mines in the Pennsylvania field.

The Philadelphia market has slowed down a trifle though there are reports of better business in most lines of industry. Prices still refuse to rise and with a greater number of mines operating on a non-union basis this alone will be sufficient to hold down spot quotations. Railway fuel is moving along at a fairly good rate. Slack appears in good supply, with all industries that use this fuel still willing to stock up on it. Tide shipments are better.

Increased demand at Baltimore about ten days ago caused an upward price movement for both better grade steam and gas coals. The resultant movement of fuel caused a drop in prices. The market has slumped off, and there have been offerings of exceptional advantage to buyers. Exports of coal have dropped behind those of September.

Some improvement in industrial demand is reported at Birmingham with gradual trend toward steadier operations at plants. Current requirements are being taken care of by buyers at present, with little tonnage for reserves. Bunker trade has improved with a fairly good tonnage being handled at Mobile, Pensacola and New Orleans from this district. Foreign shipping is taking the bulk of the fuel bunkered. Steam prices are steady and domestic quotations are about to show some changes in November.

### Mild Weather Handicaps Anthracite Trade

Encouraged by weather conditions, New York consumers of anthracite continue to buy slowly. Wholesalers and producers are kept busy endeavoring to prevent an accumulation of the various sizes and persuading retailers to take additional tonnages of sizes for which the demand is slow. Independent quotations remain steady, but this is attributed in most part to smaller receipts due to the mines being idle on Mitchell Day and All Saints' Day and to intermittent labor troubles. Egg is moving better than for several weeks, due to consumers taking it in place of stove when informed of the shortage of the latter size. Pea and chestnut continue in slow demand. There is plenty of the former to be had and several loaded boats dot the New York harbor.

Activity in the retail trade at Philadelphia quickly fell off during the week owing to the mild temperature. The mines are fast recovering from the flood, but are far behind on orders for stove and nut. Retailers have fair stocks. Pea and egg are quiet; barley is well taken, and buckwheat and rice are in easy supply. Company producers have not made any price increase for November. Independents have been slow to announce prices, but they probably will add something to stove and nut.

A reminder of winter at Baltimore has brought increased ordering from householders. Dealers report the demand for stove as the most active, with egg and chestnut running next in demand. The usual difficulties of disposing of pea and buckwheat for household use are being encountered.

Buffalo retailers are concerned over the number of oil-burning homes in the city, though natural gas is eating into the hard-coal trade most of any of its competitors. Nevertheless there is the usual shortage of stove coal and the consumer refuses to be convinced that he can use any other size in place of it. The demand for coke does not improve much in spite of the effort to push it.

## Foreign Market And Export News

### General Outlook Better in British Market But Steam Coals Still Lag

The Welsh steam coal trade is not more active though there are signs of a probable improvement in the near future. Anthracite is in demand, and collieries producing this coal cannot keep pace with the requirements in spite of the fact that output is mounting. The depression is confined almost entirely to steam coals. Many of the steam coal collieries are still working less than half time, and several pits have been stopped for as much as eight or nine days in succession, although not definitely closed down. The general outlook has improved slightly, because buyers, who have been holding off for a long time in the hope of forcing prices lower, are now coming on the market.

A few inquiries have been circulating in Newcastle during the past week, but none is sufficient to alter the general position of the market, which remains dull and easy with ample supplies of coal. The Bordeaux Gas Works has placed contracts through French firms for the supply of about 8,000 tons of Durham gas coals. The Egyptian State and Sudan railways are in the market for 200,000 tons; Sao Paulo Ry. 85,000; the British Admiralty, 300,000 to 400,000; the French navy, 43,000. The Palermo Gas Works has invited tenders for 5,000 tons of Holmside or Wear special gas coals for shipment to Palermo during early December.

The Northumberland coal mining ascertainment of the proceeds and costs in the months of June, July and August, which regulate wages in October, shows that there was a surplus of £228,216, of which 88 per cent, or £200,830, was applicable to wages and 12 per cent, or £27,386, to profits. The total wages for the current month would equal 75.58 per cent on the 1879 basis, but under the National Agreement wages cannot be lower than 100 per cent on that basis.

Production by British collieries dur-

ing the week ended Oct. 18, a cable to *Coal Age* states, was 5,147,000 tons, according to the official reports. This compares with 5,088,000 tons during the week ended Oct. 18.

#### Hampton Roads Market Weak; Foreign Movement Gains

The market at Hampton Roads is somewhat weaker, with a falling off in movement and with demand generally reported somewhat lighter, due to mild weather and other causes. Foreign movement shows a slight increase, but coastwise and bunker trades are barely holding their own.

Dealers report that the market probably would not hold even its present strength but for the slow-up in shipments from the mines to tidewater. Accumulations at the piers are below normal, due more to lack of shipments than to undue demand for cargoes.

The outlook for better business is bright, but dealers do not anticipate any material change in prices.

#### French Coal Consumption Low But Prices Are Steady

In the French market the consumption of industrial coals remains slack and that of domestic fuels slightly lower, but stocks are not important and prices keep steady.

Imports of Cardiff coals during the week have been below normal. Despite the pressure of exchange, slight concessions have been made on c.i.f. prices, but they are still too high to attract much business. Purchases of house and anthracite coals are extremely limited.

The recent decline of 10 per cent in the mine price of German coal caused some apprehension for a while in the French collieries, as it was feared that the market would be overrun with the German product, but German prices

are still too high to bring any dangerous competition. Now that the Franco-Belgian régime has ceased to operate, however, it is likely that transportation costs will be cut by the Germans, and thus increase competition.

## News Items From Field and Trade

### ALABAMA

The Pittsburg & Southern Coal & Iron Co. has sold to C. M. Green, of Birmingham, approximately 600 acres of mineral lands in Sec. 6, Tp. 16, Range 2 West, and in Sec. 1, Tp. 16, Range 3 West, located near New Castle, Jefferson County, for a consideration of \$50,000.

The long drought in the Birmingham district is causing a serious problem in coal-mining operations where washeries are employed. The supply of water from the smaller creeks and branches is insufficient to meet the needs at many points, and inconvenience and delay are being experienced in the coal fields on this account.

### ALASKA

A heavy coal deposit in northern Alaska, north of the Endicott range, has been reported to Washington by Philip S. Smith, geologist for the U. S. Geological Survey, who has recently returned from a long exploration trip in that region. The foothills and valleys north of the Endicott range contain great bodies of coal, indicating that Alaska, in past ages had a temperate, if not subtropical climate producing coal-forming vegetation unknown in the region now, he concluded in an interview at Seattle just after returning.

### COLORADO

Wm. B. Lewis of New York City president of the Oakdale and Alamo Coal companies, was in Colorado last week, where he inspected his holdings in this state, which included the Oakdale and the new Alamo mines in the Walsenburg district. The latter mine is considered the most up-to-date mine west of the Mississippi.

### ILLINOIS

The Niantic Coal Co., operating a mine ten miles west of Decatur has resumed operations.

The Fallon Coal Co. with mining property at O'Fallon, is in trouble with certain of its stockholders who live in and near Bay City, Mich. They have filed a petition in the Tuscola County district court asking an accounting of the funds and a dissolution of the company.

In a prize name contest the new employees magazine of the Southern Coal, Coke & Mining Co. gets the title "Yours and Mine." Several hundred names were suggested by employees, customers and friends of the company.

The magazine evidently aims to be a real employees' paper, for it publishes even kicks of employees against the company, together with fitting answers. The November issue is to be "election number."

The Valier mine, in southern Illinois, built by Carl Scholz and owned and operated by the Burlington R.R., is hanging up new production records which are worthy of note. On Oct. 29 this mine, long rated in the 6,000-ton class, hoisted 7,704 tons, which is its own "farthest north." On the Monday previous it had set a new record for itself by producing 7,127 tons. And to prove that the men did not hold back a lot of coal on the day before the grand burst of Oct. 29, it is reported that the mine hoisted on the 28th 7,096 tons, which would not leave much chance for a charge that the mine had been "loaded" for the big run next day. On the big day 1,740 pit cars were dumped in an 8-hour day in which 38 minutes time was lost. F. F. Green is superintendent of this mine and Charles E. Anderson, underground manager.

A large mule barn was burned down Saturday night, Oct. 25 at the Paradise Coal Co.'s mine at Duquoin. Luckily the wind was low and the fire did not spread to any of the adjoining top buildings. Several tons of hay and a number of mine mules were lost.

George Adams, of Matherville, has been appointed as mine manager for the mine of the Rex Coal Co., at Coal Valley, filling a vacancy caused by the death of Thomas Mills.

The weigh office in the tippie and a portion of the tippie itself at the Harco mine, near Harrisburg, was destroyed by fire Oct. 23. Several hundred men employed at the plant will be idle until repairs can be made.

Frank F. Tirre was recently appointed general manager and is in charge of the St. Louis office of the Mulberry Hill Coal Co. The company is now handling its own distribution. Its property is the Mulberry Hill mine near Belleville.

According to reports compiled by County Mine Inspector John O'Brien, of La Salle County, a total of 575,652 tons of coal was mined in that county last year. The men employed in the mines during the period numbered 971, the mines working an average of 166 days during the year.

The total output of mines in Illinois was 72,308,655 tons during the fiscal year ending June 30, 1924, according to reports compiled by Martin Bolt, Director of the State Department of Mines and Minerals of Illinois, at

Springfield. The report indicates that over 70,000,000 tons was produced by shipping mines, the balance by local and wagon mines in small amounts.

A small loss was sustained by the Scott-Smith Coal Co. Oct. 26 when the office and weigh room of its strip mine, near Duquoin, was burned. The fire was of unknown origin.

### KENTUCKY

It was reported from Owensboro on Oct. 18 that one man was killed and four injured, in a heavy slate fall at the Rockport Coal Co. mine at Centertown. It was stated that the cage fell, and in doing so dislodged a lot of slate from the sides of the shaft.

### MASSACHUSETTS

The Island Creek Coal Co. reports net profit of \$478,900 for the third quarter of 1924, compared with \$623,634 in the corresponding period of last year. For the nine months the company earned \$1,915,774 available for the common stock, compared with \$1,984,864 last year. The company mined 1,424,409 tons of coal in the third quarter of this year, compared with 854,728 last year, but its gross profit was only \$747,420 in 1924, compared with \$859,985 in 1923.

### MONTANA

Meagher County is considerably wrought up over a report that Eastern capital, possibly Henry Ford's, has bought up a large acreage of iron land in the Sheep Creek territory and that a blast furnace and steel mill will soon be erected either in Meagher County or in Great Falls, consuming a heavy tonnage of Montana coal.

### OHIO

The Kentucky River Coal Sales Co., with headquarters in Chicago, has closed the Cincinnati branch office it had maintained for nearly two years on the sixth floor of the Dixie Terminal Building.

Paul Barnett, formerly a banker in the Logan (W. Va.) district, is now associated with the Cincinnati office of the Raleigh Smokeless Coal Co. learning the business end of the coal industry.

Foreclosure proceedings have been instituted by the bondholders on the property of the Maynard Coal Co., of Columbus, which was forced into the hands of receivers about six months ago. The bondholders will soon obtain an order of sale and the various prop-

erties will be advertised by the receivers. W. S. Harmon and Frank L. Stein. The properties consist of large coal mines in the Pomeroy field, Ohio, and the Hazard field in Kentucky.

Under order of court the property of the Dean Coal & Coke Co., which had offices in Columbus, were offered for sale by Receiver Ralph E. Marburger Nov. 3. The property, which was forced into the hands of receiver about eight months ago, was appraised at \$20,516.50.

The Sixty-Eight Mining Co., recently chartered with 750 shares of stock, no par value designated, has been organized by the election of A. R. Jones, president, George Gibbs, vice-president and H. E. Cleary, secretary-treasurer. The company has two operating mines near Athens in the Hocking Valley field. Offices are located in the Stoneman Building, Columbus.

## PENNSYLVANIA

On October 27 the blacksmith shop of the Connellsville Central Coke Co.'s Herbert plant was completely destroyed by fire. The plant had been idle for several months, but the shop will be rebuilt at once.

The Derry No. 1 plant of the Latrobe-Connellsville Coal & Coke Co., located at Bradenville, resumed operations Oct. 27 after a shutdown of almost a year. The plant was scheduled to resume operations last spring when an order for railroad coal was obtained, but after placing the order the railroad deferred taking any coal. The mine has been put in first-class condition and has been equipped with coal-cleaning apparatus. The mine will give employment to a large number of men, most of whom are former employees.

Mining operations at the No. 10 slope of the Lehigh Valley Coal Co. near Drifton are to be discontinued in the near future. The men now employed there will be given jobs at other plants of the company.

Purchase of coal lands in North and East Union Townships by the South Penn Collieries Co., of Philadelphia, according to the revenue stamps on the deeds, recorded Oct. 25, involved \$400,000. The sellers were as follows:

Jennie J. Dull, in East Union Township, for which was paid \$172,000; William H. Shepp, in North and East Union Townships, for \$140,000; Rachael Deeber, in East Union for \$88,000.

For the first time in the history of district 9, every man and boy employed in and about the mines is enrolled as a member of the United Mine Workers, President Golden of the district reports. The 100 per cent enrollment is attributed to the shift made two years ago from local unions to colliery locals, the change permitting a closer supervision of the various employees.

The Pennsylvania Coal & Coke Corp. for the quarter ended Sept. 30, 1924, reports a deficit of \$147,547 after depreciation and depletion, but before federal taxes, against a surplus of \$159,957 in the third quarter of 1923. The deficit for the first nine months of 1924 totaled \$288,655 after charges, but before federal taxes, against a surplus of \$741,963 in the same period of 1923. Federal taxes for nine months are estimated at \$8,000.

The first labor temple to be erected by the United Mine Workers in the anthracite field was dedicated on Mitchell Day, Oct. 29, at Olyphant. The building was purchased and remodeled to serve the purposes of the union, by four locals in the town of Olyphant at a cost of \$25,000. District President Thomas Kennedy, of District 7, made the dedication address.

Visitors from various parts of the United States, Canada, Great Britain and Czechoslovakia recently inspected the gravity coal-cleaning plant that serves several mines of Peale, Peacock & Kerr, Inc., one of the largest producers in the district.

Boyd C. Osler, chief engineer of the Hazle Brook Coal Co., Hazleton, has resigned to become general superintendent of the newly organized Shamokin Coal Co., which is reopening the old Neilson colliery, near Shamokin.

All of the collieries in the anthracite field were idle on election day. The miners were instructed to get out and work for labor candidates in the various districts during the day. The political activities by the union men were especially manifested in District 1.

The Harleigh Coal Co., which is

erecting a washery at Harleigh, is preparing to have the steel work installed. The Lehigh Valley R.R. is extending its tracks to the washery. Once the plant starts to operate the refuse is to be dumped into the abandoned strip-pings near by. The Harleigh Coal Co. is composed of Freeland, Scranton, and New York capitalists.

A high powered electric engine has been installed in No. 4 slope, Alaska mine, of the Philadelphia & Reading Coal & Iron Corporation in Shamokin. This slope is 2,400 ft. long. The present engine is able to haul but three cars up the slope and ten minutes is required to finish the trip. The more powerful engine will haul four cars and will complete the trip in two minutes. Officials expect that with the increased pulling power the output of the mine will be greatly increased.

E. Kent Davis, chief engineer of Peale, Peacock & Kerr, at St. Benedict, will speak at the next session of the Pennsylvania Coal Mining Institute, which will be held Nov. 21. The announcement was made at the opening session of the fall and winter season at Johnston last week.

Secretary James W. McAndrew, of District 9, United Mine Workers, at a session of the biennial convention of the district at Shenandoah, reported that the district membership of the organization on Dec. 1, 1923, broke all records, reaching a total of 56,440½ paid-up members and an exonerated list of 2,796, making a grand total of 59,209½. The two-year average of the union was announced at 37,309, with an exonerated list of 3,073. The district collected a total of \$227,468.46 with expenses of \$158,379. The balance in the treasury of the district Oct. 1, this year, was \$142,759.45. The change from local unions to colliery locals resulted in the reduction of the total number of locals from 162 to 89.

Unity of practically all major interests in the central Pennsylvania field in the matter of labor policy is assured by the announcement that the Pennsylvania Coal & Coke Corporation and the Clearfield Bituminous Coal Corporation are again members of the Bituminous Coal Operators' Association of Central Pennsylvania.

Union officials from both the anthracite and bituminous fields of the state will meet in Harrisburg Nov. 12 and 13 to draft a program for presentation at the next session of the Legislature. The miners want an old age pension law as well as certain changes in the mine safety laws and the workmen's compensation act.

## UTAH

The Consumers' Mutual Coal Co. is planning to mine and ship coal from its property in Carbon County about Dec. 13. It owns 1,800 acres of coal land in the county. The mine will be equipped to produce 2,000 tons daily, it is stated, but the initial production will be far less than that. Loading machines and belt conveyors will be used. There will be no cars, except for carrying supplies. The Consumers' is the newest coal mining concern to be started here on the mutual plan. It purchased the yard of

General Office and Bank, Phelps Dodge Corporation

Located at the coal mines of the company, in Dawson, N. M., it conforms in degree with the style of architecture of old Mexico.

the Dunyon Coal Co., of Salt Lake City, for the purpose of distributing its coal locally.

The application of the Diamond Coal Co., of Salt Lake City, for permission to sell 100,000 shares of stock at 10c. a share has been held up by the Utah Securities Commission until sufficient work has been done on the company's property to show the grade of coal and the thickness of the bed. The property is located in the American Fork Canyon, Utah County.

The State Industrial Commission has placed two men on duty in the Spring Canyon district, where the Rains mine blew up in September, and it is stated they will be kept there until rock dusting and the erection of rock barriers in all mines in that district have been completed. These men are making regular inspections of the mine, it is stated, and by co-operating with the operators are keeping the men keyed up on safety. The mine department of the commission, which is consolidated with the local office of the federal Bureau of Mines, has not yet issued its report concerning the cause of the Rains explosion.

## WASHINGTON

The new mine of the Black Carbon Coal Co., near Buckley, got into operation with a formal opening Oct. 15. It is electrically equipped and has a capacity of approximately 300 tons a day. A washery is located at the mine. Fraser H. Lantz is president and general manager and David Gray is superintendent.

An attempt to interest English shipping interests in coaling ships at the Pacific Coast Coal Co. bunkers in Seattle has taken Wylie Hemphill, sales manager of the coal company, to England on a trip on which he is accompanied by Mrs. Hemphill.

## WEST VIRGINIA

The name of the Waddles Run Coal Co. has been changed to the Washington Heights Improvement Co.

The Beluan Coal Co., chartered under the laws of Ohio, of which C. A. McFadden of Wheeling is president, has been authorized to transact business in West Virginia, as has the Consolidated Coal & Oil Corporation, chartered under the laws of Delaware.

The following West Virginia coal concerns have surrendered their charters to the Secretary of State of West Virginia: Guyan Coal & Coke Co., Corrado Fairmont Coal Co. and the D. T. S. Coal Co.

The Quincy Coal Co. has moved its principal office from Charleston to Quincy.

The United Mine Workers has instituted suit in the Circuit Court of Marion County for \$50,000 damages against the Brady-Warner Coal Corporation, charging that the coal company was responsible for the destruction by fire on June 19 of the present year of the miners' hall at Brady. The hall burned down during a clash between union miners and men engaged in guarding

the company's property. It is contended by the union that the company guards set fire to the building. There are two separate suits of \$25,000 each.

The Pocahontas Fuel Co. has announced a resumption of operations at its Itmann mine, in Wyoming County, which has been shut down for several months. This is one of the largest operations in Wyoming County and the company recently completed construction work on a model store building, constructed of native stone taken from the mountains surrounding the property.

Several companies which recently began operations in the Kanawha field on an open-shop basis are increasing production. The Campbells Creek Coal Co., which has been operating union mines for several years, is now shipping about 800 tons a day out of the Campbells Creek field via Dana, and the New Export Coal Co. has a production of about 400 tons a day. The Winifrede Coal Co. also is managing to increase production inasmuch as it is now loading about 1,000 tons a day at its mines out of Winifrede Junction on the Kanawha River.

The Philadelphia-Cleveland Coal Co. has just completed a new coal-loading dock and tippie in Huntington representing an outlay of \$250,000. The dock will have a capacity of 5,000 tons per ten-hour day and more than a million tons a year. In loading coal from cars to barges the company uses a large stationary conveyor, a movable conveyor and a pan conveyor. The company has its own dummy engine for placing loaded coal cars. All machinery is operated by electricity.

## WYOMING

The old mine at Point of Rocks, east of Rock Springs on the Union Pacific, is to be opened again. M. Mitter, of Denver, head of the Rock Springs Coal & Mining Co., says he has a contract for 140,000 tons of coal and will start the mine soon. A spur track must be rebuilt to the mine if any coal is to be taken out. The mine has been operated for short periods by several owners in the past.

## CANADA

Roy M. Wolvin, of Besco, president of the British Empire Steel Corporation, intimated during his recent visit to Cape Breton, that he would welcome early negotiations with the coal miners for a new wage scale to take the place of the one that expires Jan. 25.

It has been decided by the Toronto Board of Education to install coal-burning furnaces instead of oil heaters in the new High School of Commerce. C. J. Doughty, superintendent of maintenance for the schools, stated that if coal were used instead of oil throughout the schools it would effect a saving averaging \$500 a year for each school.

Importation of bituminous coal into Canada from the United States fell from 15,729,578 tons during the twelve months ended September, 1923, to 13,319,130, during the twelve months ended last month. Anthracite importa-

tion fell, during the same comparative periods, from 5,090,567 tons to 3,897,662 tons. Owing largely to industrial conditions in Alberta the exportation of Canadian coal to the United States fell from more than 7,000,000 tons during the twelve months ending September, 1923, to 2,325,676 tons during the past twelve months.

Some important changes have been made in the directorate of the British Empire Steel Corporation and constituent companies. Senator Lorne C. Webster, of Montreal, has been appointed a member of the board, and Viscount Furness and Benjamin Talbot, two of the British directors, have resigned. The reason assigned is that they are unable to attend the board meetings.

It having been alleged that the coal dealers of Winnipeg have entered into a price regulating agreement, under which customers have to pay more than they otherwise would, and are engaged in a movement to eliminate competition by cutting off sources of supply to those refusing to maintain a fixed price, an inquiry has been ordered under the Combines Investigation Act. D. Campbell, K.C., of Winnipeg, has been appointed a commissioner to investigate the alleged combine.

Coal production in the Telkwa Valley, northern British Columbia, again is promised. With the coming of winter and the increased domestic demand in Prince Rupert and other communities along the line of the Canadian National Ry. some of the Telkwa coal seams will be exploited. The Telkwa Coal Mines, it is reported, already has started work and expects to be in a position to supply most of the local requirements.

## Trade Literature

**The Lincoln Greasing System for Mine Cars.** Lincoln Steel & Forge Co., St. Louis, Mo. Pp. 7; 8 x 11 in.; illustrated. An outstanding feature of this system is that it permits a central greasing station either underground or on top where the cars may be greased in trips as they pass the greasing machine.

**K and K Flotation Machine.** Southwest Engineering Co., Los Angeles, Calif. Catalog D. Pp. 36; 7 x 10 in.; illustrated. The special features of this machine are described and pictures of it in operation are shown.

**Hyatt Roller Bearings for Conveyors.** Hyatt Roller Bearing Co., Newark, N. J. Bulletin No. 1015. Pp. 23; 8 x 11 in.; illustrated. Describes the part these bearings have and will play, when properly selected and assembled, in reducing to a minimum the operating expenses of a conveying system.

**Electric Elevator Control Equipment.** The Cutler-Hammer Mfg. Co., Milwaukee, Wis. Publication 2082. Pp. 48; 8 x 11 in.; illustrated. Different types of elevator control apparatus for passenger and freight elevators are described.

**American H. S. Fans.** American Blower Co., Detroit, Mich. Bulletin No. 1103. Pp. 35; 8 x 11 in.; illustrated. Some of the distinguishing features of these fans which are described include the streamlike design of air entering orifices or blower inlets; the impellers or wheels are designed so as to keep a uniform velocity of air through the wheel, thereby reducing wheel loss; two single-inlet impellers or wheels to each blower of the double inlet type; specially designed scroll or casing with expanding outlet, so proportioned as to afford maximum recovery from velocity pressure to static pressure with the least amount of turbulence. Curves, specification sheets and tables are included.

## Traffic

### B. & O. Assails Indiana's Low Intrastate Rates

Copies of the complaint by the Baltimore & Ohio R.R. and other steam roads operating in Indiana, against the Indiana Public Service Commission's reduced schedule of intrastate coal rates now effective in that state, which has been filed before the Interstate Commerce Commission, have been received by Governor Branch of Indiana and the Indiana commission. The roads charge in their new attack on rate schedules on coal, which they failed to displace by court appeals, that the rates cause undue discrimination against interstate commerce. An investigation has been ordered by the Interstate Commerce Commission and it is expected that a date will be fixed in December for a hearing by an examiner, probably in Indianapolis. The Indiana Public Service Commission, as principal defendant, will work for the dismissal of the new case filed by the roads.

### Freight Rate on Coal Reduced In Clarksburg District

The West Virginia Public Service Commission has issued an order reducing the freight rate on coal in the Clarksburg and first freight zone of West Virginia, effective Dec. 1. This is the second reduction within the last two years. Directly the new rate applies to the Baltimore & Ohio, Pennsylvania, Monongahela and Western Maryland railroads, but other railroads in the state are affected indirectly as well.

The case was known as No. 1,307 on the docket of the commission and was brought before the commission on the petition of the Domestic Coke Co., of Fairmont, to investigate and determine the reasonableness of rates now in effect on the transportation of all kinds and classes of freight, including coal and coke, by carriers on steam railroads between points within the state on short hauls. Under the ruling of the commission all the railroads above enumerated are required to put into effect on Dec. 1 a rate not to exceed 55c. per net ton on coal transported from mine or point within the first zone to another point within that zone. The Baltimore & Ohio is required to put into effect a rate not to exceed 42c. per net ton on coal transported within the Clarksburg district and the same road also is required to put into effect a coking-in-transit rate not to exceed 40c. per net ton within the first zone.

## Industrial Notes

The Newark Wire Cloth Co., Newark, N. J., has established a new branch office in the New England States at 66 Hamilton St., Cambridge, Mass., with John G. Loring in charge. A new factory of over 30,000 sq. ft. ground area has just been completed on Verona Avenue in Newark.

The Conveyors Corporation of America, 326 West Madison Street, Chicago, announces the appointment of W. P. MacKenzie Co., 1234 Callowhill Street, Philadelphia, as its sales representatives in southeastern Pennsylvania and southern

New Jersey. This organization will handle the sale of steam jet ash conveyors, cast-iron storage tanks, airtight doors for ash-pits and boiler settings, and other specialties. Associated with W. P. MacKenzie in the sales organization are John Beard, J. E. Fulweiler, S. T. MacKenzie and W. R. Lunn.

## New Companies

The Dozier-Diamond Coal Co. has been incorporated in Madisonville, Ky., with a capital stock of \$20,000, by W. B. Dozier, Jesse Diamond and E. W. Dozier. Jesse Diamond previously was moving spirit in the Southern Gem Coal Co. in Illinois, now defunct.

The Gregory Branch Coal Co. has been incorporated in Grays, Ky., with a capital stock of \$50,000, by J. T. Gray, H. E. Hubbard and others.

The Elliott & Day Coal Co. has been incorporated in Pikeville, Ky., with a capital stock of \$10,000, by W. K. Elliott, P. W. Day and others.

W. R. J. Zimmerman, of Charleston, W. Va., well known in the coal business, has just launched a new company to be known as the Zimmerman Coal Co. Associated with him in the new concern are: R. S. Spillman, F. L. Thomas, H. H. Corri and H. D. Battle, all of Charleston. The company has an authorized capital stock of \$50,000.

A charter has been issued by the Secretary of State of West Virginia to the Beury Brothers Coal Co., capitalized at \$100,000. T. C. Beury, John A. Thayer, Beverly Broun, Edward Hart and George R. Bullock are the incorporators. The property to be operated is a part of the old Beury lease near Echo, W. Va., and is said to contain a large amount of good coal.

A state charter was issued recently at Harrisburg, Pa., to the Clift Coal Co., of Wilkes-Barre, the purpose of which is mining, shipping, selling, purchasing, leasing and dealing in coal. The capital stock of the company is \$500,000 and the incorporators are W. O. Washburn, 51 North River Street, Wilkes-Barre, treasurer; Charles E. Clift and W. J. Fowler, Wyoming.

## Association Activities

At the third semi-annual meeting of the Moshannon Coal Mining Institute held in Philipsburg, Pa., late in October, President Thomas A. Mather presented an interesting program of talks on mining problems. H. I. Smith, of the U. S. Bureau of Mines, gave a highly interesting discussion on the subject of leasing of government coal lands. Officers were elected as follows: President, R. H. George, Winburne; vice presidents, W. A. Gould, Philipsburg; Albin Lindberg, Allport, and Thomas A. Mather, Tyrone; secretary-treasurer, Thomas F. Morgan, Philipsburg; assistant secretary-treasurer, William George, Philipsburg; executive board, Summerville Eastment, Philipsburg; Thomas Gallagher, Houtzdale; Joseph Knapper, Philipsburg; H. McD. Lorain, Philipsburg, and James Marshall, Houtzdale. There were 133 members and guests present.

## Coming Meetings

Illinois Mining Institute. Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

American Society of Mechanical Engineers. Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

West Virginia Coal Mining Institute. Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Coal Mining Institute of America. Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

## New Equipment

### Automatic Reclosing Breaker Operated Manually

Automatic reclosing circuit breakers have long since emerged from the class of new devices. In certain fields, notably in coal mines and electric railways, they have an established place as one of the devices essential to efficient operation. In other fields and in industrial plants generally, were interruptions due to overloads and short circuits are not so frequent, automatic

### Reclosed Automatically or Manually

Should this breaker fail to function because something has gone wrong with the automatic reclosing control features it may easily be operated manually.

reclosing circuit breakers have not been so generally adopted. The reason for this probably has been that the advantage of the automatic reclosing feature has not been sufficiently apparent to offset the thought that an automatic reclosing circuit breaker is more complicated than a manually operated breaker. Also, no doubt, there has been considerable hesitancy in the past in applying automatic reclosing breakers to important feeders in mills and industrial plants because of some doubt as to what should be done in the event that the circuit breaker failed to operate automatically.

In order to overcome these objections and obstacles to the more extended use of automatic reclosing breakers, The Automatic Reclosing Circuit Breaker Co., of Columbus, Ohio, has recently developed a circuit breaker which normally is full automatic in its operation but it may at any time be operated in the same manner as a manually operated breaker.

When operating as an automatic re-

closing circuit breaker, it is under the control of a double-pole push button switch. When this switch is in the "off" position, all of the control circuits of the breaker are completely disconnected and the breaker remains open. When the switch is in the "on" position, the control circuits of the breaker are connected and the breaker closes, provided conditions on the line are proper for it to do so. On overload, it opens automatically, remains open a short time interval regardless of load conditions, and at the expiration of the predetermined period recloses, providing the overload or short circuit which caused it to open has been removed.

When for any reason whatever it is desired to operate the circuit breaker manually, the control switch is thrown in the "off" position and the operating handle attached to the breaker. The breaker is then closed in the usual manner by depressing the handle. It will open on overload or voltage failure if provided with no-voltage release. The operating handle is removed when the breaker is again placed in automatic operation.

Thus refinements of automatic control are attained, coupled with assurance of high-grade circuit breaker protection at all times and under all conditions. At the present time, breakers of this type are available in capacities up to and including 2,000 amp.

### Semi-Automatic Starter

A new and improved resistance starter for squirrel-cage motors up to 30 hp., 220 volts and 50 hp., 440 to 550 volts has lately been brought out by

**Stepless Motor Starter**

Smooth starting characteristics are obtained by compression of graphite resistor disks. The motor is thrown across the line without breaking the starting circuit.

the Allen-Bradley Co., Milwaukee. Stepless acceleration and smooth increase in starting torque without excessive starting current is provided by using the well-known graphite compression resistors which provide a starting cycle smoother than is obtained with any form of transformer compensator. The motor is started by lifting the starting handle quickly to the mid position. From that point the handle is slowly lifted and the magnetic switch closes, thus throwing the motor on the line without opening the motor circuit. Arc shields and blow-outs are provided in all phases.

### Well-Balanced Air Compressor Mounted on Mine Car

A marked advance in portable equipment for underground mining, and one in which coal-mine operators, particularly, are showing considerable interest, has been made in the newly designed Type 20 mine-car air compressor recently placed on the market by the Ingersoll-Rand Co.

### Plenty of Air Must Be Available If Work Is To Be Done Promptly

Pressure losses and delays caused by long pipe lines are obviated by setting-up the compressor near where hammers and drills are used. A short wheelbase truck is always essential on such equipment so that it can turn short curves. However, the compressor and drive must be well balanced to prevent vibrations.

speed and of greater capacity. Furthermore, they required less floor space; and a simple foundation sufficed to assure their alignment.

With a gradual improvement of the air compressor, its value to industry increased; and it was inevitable that there should arise a demand for a portable machine—one that could be moved easily and quickly from place to place and that would always be ready for service. The usefulness of compressors of this type need not be elaborated here.

Portable mine-car compressors are nothing new; but, appreciating the exacting nature of the work, the company in question set itself the task of carefully studying the conditions under which machines of this sort have to operate and then of designing equipment that would best meet those requirements. The new Type 20, electrically driven, mine-car air compressor is the result.

The compressor is of the vertical, duplex type. Its natural tendency to vibrate is along the vertical plane, and this has been counteracted by centering the compressor over one of the axles—giving it, in effect, a solid foundation. The electric motor, which is of extra-heavy construction and built to resist vibration, is connected to the compressor by means of a quickly detachable coupling. The whole equipment is mounted on a rigid, cast-steel frame, to the underside of which are attached mine-car wheels on short centers to permit taking sharp curves.

This self-contained mine-car compressor is being manufactured in three sizes, namely: 91, 160, and 230 cu.ft. per minute piston displacement.

### New Plymouth Gasoline Locomotive

The Fate-Root-Heath Co., formerly the Plymouth Locomotive Works, Plymouth, Ohio, has just brought out a new gasoline locomotive. It weighs eight tons and is equipped with a Climax four-cylinder engine developing 85 hp. at 900 r.p.m. Bosch high-tension magneto with impulse couplings, Simms 12-volt starter, Willard storage battery, Stromberg carburetor, United air cleaner and built-in governor.

Cooling is by a means of a Modine sectional-core radiator and a 22-in. gear-driven fan. The radiator is protected by a heavy guard. The power transmission is the well-known sliding-gear type providing four speeds forward and one reverse.

Axles are of alloy steel, heat treated and of extra large diameter. Wheels are rolled steel, 24 in. in diameter. Brakes are of the lever type to all four wheels and sand is applied by hand to all four wheels.

This locomotive is built with a high cab, the height over all being 84 in., enabling the operator to see over industrial cars. The cab is provided with a side entrance with sliding steel doors, avoiding the danger from exit between the locomotive and car, as in the case of rear-opening types.

The operating speeds are 2½, 4, 8, and 12 miles per hour, with an engine speed of 900 r.p.m. The drawbar pull at 2½ m.p.h. with sand is 6,000 lb.

## Eliminating the Janitor

**F**OREMOST among the reasons advanced for the use of oil in place of coal for domestic purposes is that the janitor is eliminated, whereas with coal it is difficult to dispense with him, the ash being in a cellar below the street level and the ashes having to be carried up to the sidewalk.

However, that difficulty would be greatly reduced if the quantity of ash were lessened by the better cleaning of coal. Ash cans of decreased height and weight might be used such as the householder, though an office man, could readily handle. In this way the cost of warming a dwelling house would be reduced about \$60 a year.

Ash in domestic coal furnishes a difficult problem to the householder. What he spends in removing it, if he hires a janitor, would enable him to buy about four tons more coal, though some householders are able to solve the problem by hiring men whose sole duty it is to carry the cans from the cellar and place them on the street or by bribing the city ash men to enter the cellar and remove the cans, contrary in most cases to the city ordinance. If the anthracite man would oust oil he can do it no better than by reducing the ash content of his product.

## All Ways Are Clear

**A**S THE result of the election the whole nation breathes more freely. The Republican and Democratic candidates for President were both men of high ideals, of excellent record and noble purpose. Of the other important candidate, La Follette, we are not disposed to speak with disfavor, but he was endeavoring to obtain office by advocating principles which would have been highly detrimental to the nation's well being and progress.

La Follette would have the railroads and coal mines operated by National commissions though every question that would confront such administrative bodies would be a political issue. The commissioners would ask: What action would menace the life of the commission? What decision would alienate the voter? Expedient political action would be the test of every question. Economy would not live long in such an atmosphere. Every problem would be solved by considerations of the moment rather than by larger questions of economical operation. As a result the industries operated by government would be inflated. Uneconomical plants would continue to be operated. Necessarily unprofitable roads would be built and maintained, and the effort of every congressman would be expended in getting favors for his own section.

We all remember how repair docks were kept in operation and extended when they could be reached no

longer by naval vessels of the size which needed repair. We know how post-offices were constructed not on the basis of population and post-office needs but in response to clamor and to make certain congressmen "solid" with their constituencies. We know how even during the war decisions sometimes were made to satisfy certain voting necessities, at places that no manufacturer would choose for such enterprises.

But these facts, though they must not be forgotten, do not now menace us. We have for four, and we believe for many, years the promise of a clear way before us in which we shall be able to direct our attention to development and progress. Industry is free once more to advance, and the sentiment is abroad that we are going to have better times, less unemployment, less uncertainty and greater rewards for all who serve the public by their activity and labor. The farmer, whose sound judgment was, for a moment, questioned, has proved to be no supporter of La Follette, nationalization, syndicalism or socialism. The public has rendered a verdict that this country is safest under constitutional rule and under a system of government which protects the weak without hobbling the strong. The prospects are brighter than were for a while expected. For this we are grateful, the more that for a time the nation had to endure an extremely inclement political atmosphere.

## Near and Far

**I**F NEWSPAPER statements are to be believed the President is going to favor railroad tariffs giving lower rates per mile to the farmers located in places distant from points of consumption, thus depriving those that are near the market of their natural advantage. The duty of providing the railroads with an adequate income is to be shouldered by those shipping less bulky products. This will arouse much opposition and may never get beyond the point of discussion.

The interest of the coal trade in this action is obvious. The high-volatile coals, having been deprived of their natural market by freight rates based on equality in transportation charges, or rather on a supposed equality in competition, instead of on distance of transportation, have been anxious to have these rates revised. It naturally will be conceded that if farm rates, which have been quite largely based on distance are now to be based on competitive equality, coal rates that have been largely based on the latter plan will hardly be revised so as to return to the former. The Interstate Commerce Commission or Congress can hardly be so inconsistent, at least in making new decisions.

Thus the battle rages, with victory seemingly veering toward those who have been led by circumstance and preference to locate in the more remote regions. As far as farming is concerned we cannot see why any

dispensation should be given to those who inhabit the rich valleys of Utah. It has never been claimed hitherto that the agriculturists around Salt Lake City needed government help and favor.

### Put the Price Too High

MUCH of the trouble with coal has been that its price has been put too high. The Coal Trust, which is a labor and not a capital trust, has made the mistake that trusts too often make. They believe they can set the price where they will, and then they place it higher than the traffic will bear.

The anthracite-miner trust has lost some business by that fact. Oil and coke have made inroads, because the anthracite wage scale was unduly boosted and prices became excessively high. In the union bituminous mines the same mistake was made, but in that case the effect on the labor trust was worse, because the consumer in many cases could buy from non-union mines.

Labor trusts can easily put the price too high. They should remember that the railroads when they held unrestrained power were disposed to ask no more than would keep business coming to their roads. They called it charging "all that the traffic would bear." They were excoriated for it, but the wrong they did was less heinous and less self-destructive than charging more than the traffic will bear. Self-advantage and responsibility to the public combine to condemn any such action.

### The Dollar Mark

MANY DOLLARS there be that will neither ring nor resist the pressure of the teeth. We cannot measure everything in dollars. For instance, what is gained at conventions and institutes cannot always be written down in hard currency, but unfortunately the cost of the trip may be so evaluated. We can write the expenditure down in serried figures. In fact most of these costs are so written, and sometimes the time cost is also thus estimated. Therein lies the danger. The rewards are intangible; but the money paid for them is so readily measured.

But if we look back into history, we shall find that the ages when men traveled, when the brightest minds met, were ages of progress and the times when men stayed at home and relied on their own unaided wisdom were days of retrogression. It is true many great men have come from closely isolated territories, but so long as they stayed closed in by mountains, desert plains, ill-constructed roads or tempestuous seas they showed the evil effects of isolation.

The convention habit is going to be one of the quickeners of civilization. Those who avoid it will still follow their several narrowed ways, full of prejudice and lacking in purpose. The convention stimulates thought, lays in fact a premium on it, gives a driving force to life. The mental muscles are stimulated by it. Functions sterile for lack of use are pricked into life, at the expense, it is true, of time, of railroad fare and hotel charges, but who shall say the cost is greater than the profit, the outlay greater than that which is laid by.

The Coal Mining Institute of America, the most numerous attended of our coal-mine meetings, meets this year with a good program, not least of all its prolific question box, which if it misses fire occasionally

always brings up much of sterling value. The papers on haulage by belt, on recent electrical development and on rock dusting will be delivered by the most competent of men. They will give those attending the meeting a new "slant" on mine operation and safety, and even better yet they will promote thought and study.

They will have ramifications in the mining industry that will be difficult to trace back, for progress in one direction gives to an active mind power to develop in other ways. No sooner is one science accelerated than all move forward together. We trust that the Coal Mining Institute of America will be well attended and that the habit of gaging the dollar by mere physical tests will be, at least temporarily, abandoned, for the difference in the quality of mind between the employer and employee rests largely in this matter of mental contacts.

### Who Excuses Himself Is His Own Condemner

OF ALL FRENCH proverbs none is perhaps more apt than *Qui s'excuse s'accuse*, which may be translated "He who excuses himself is his own accuser." The best manner of meeting a possible accusation is by establishing a good reputation and doing it before the charge is brought. Then when the public hears unfavorable comment it has its mind already made up and meets the accusation with the words: "It cannot be true or if it should be true there are extenuating circumstances. Let us wait to hear the whole matter. You will see then what you shall see."

The very worst time to answer a charge is when the charge is made. The public accepts what it hears first, and to dislodge a formed prejudice is many times as hard as to put an idea in an unprejudiced mind. That is the trouble with the coal industry and with the coal companies individually. The industry and the companies go along silently, always "out" to callers, always silent as to their good deeds, always unwilling to give information as to their progress—and then a charge comes. The industry or the company is arraigned; it has been callous as to the rights and comforts of its employees, it has been ill-disposed to progress and the charge is unanswerable, not because there is no defense but because the judge, the public, is too lazy or too prejudiced to listen. The brain cells of the hearer have already grouped themselves and the reply is "You will have to show me."

We have in mind some corporations, incensed at criticism and rightly so, which, nevertheless, keep their lights under an impenetrable bushel. Will their good deeds serve them? We think not. We recall on the other hand two manufacturers who gave the press good opportunity to learn about their humanitarian work, their *bonhomie*, their aggressive methods in promoting safety and economy. Later came ominous charges against one of them, frequently repeated, but the public would not hear them. The people even gloried in their profits. The manufacturer thus bitterly attacked made no defense. He did not need to do so. The good he had done, which the public knew and recognized, carried conviction with it. One of the railroad companies attained a similar repute and not only did it save its reputation but it gave its president such a standing that no matter what was said—and much indeed was said against him—he continued in public favor and still retains much of it.

# H. S. Gay Long Ago Tried Out "Modified Longwall"

His 1905 Efforts at Full Retreating Longwall Failed Because of Uncontrollable Roof But Rib-Slabbing in Rooms 300 x 80 Ft. Was Safer and Raised Output to 9.2 Tons a Day per Inside Employee

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*  
Pittsburgh, Pa.

ALTHOUGH many coal-mining men still scoff at those who ponder the possibilities of converting room-and-pillar mines to modified longwall methods, it is a fact that the ranks of the longwall thinkers are thickening. Longwall mining in one modified form or another has been adopted in many an American mine, following trails blazed by such men as Harry S. Gay, Sr. So his longwall experiments of 20 years ago are coming to have a new interest for coal men of today.

As early as 1905, in Logan County of West Virginia, Mr. Gay, then an active mining engineer but now a resident of Baltimore, Md., began his trail blazing. He wrote at the time: "Not having the vision of a prophet, I determined on the first suitable opportunity to try some system of modified longwall." After following his profession for a number of years in the anthracite field of Pennsylvania, in 1904 he had moved to

Logan, W. Va., where he opened up the Gay mine of the Gay Coal & Coke Co. The following year he started an experiment that was destined to modify longwall mining so as to meet the conditions imposed by the market and the particular seam to be worked and to make it less costly than room-and-pillar work.

The Gay mine was opened up in a tract of the Cedar Grove seam (known as the Island Creek seam in Logan County), lying 200 ft. above the level of the Guyan River and dipping southwesterly about  $1\frac{1}{2}$  per cent. In this tract the average thickness of the seam is 67 in. The coal in the old sections of the mine where the early experiments were made is free of partings. Above it the cover attains a maximum thickness of about 1,000 ft., the average being about 500 ft.

## ROOF WAS SOUND BUT DIFFICULT TO CONTROL

When the experiments were first started, the field being new, little was known about the character of the roof except that it was apparently sound. The few previous experiments in applying a longwall system in mining West Virginia seams were without success because the action of the roof could not be controlled. Realizing this difficulty, portable posts were designed by Mr. Gay to support the roof near the face of the workings and to obviate the immense supply of timbers which his experiments otherwise would have required. Details of this type of post, save that it was mounted on a heavy hydraulic head, and supported a heavy roof

load, are of no immediate importance because its use was discontinued long ago.

It was proposed to mine by a longwall retreating system the block of coal given to the first experiment. Accordingly, the section shown in Fig. 1 was developed by the two longitudinal sets of entries, Nos. 4 and 5, and the No. 2 transverse set of entries, which laid off a block 300 ft. wide and 600 ft. long. The aircourses and haulage entries were driven 10 ft. wide and were separated by a pillar 60 ft. wide.

As the retreating wall moved away from No. 2 entry, the span of roof left behind did not break freely, but tended to act as a cantilever over the face of the coal. After this wall had retreated more than 30 ft., rows of props on 15-ft. centers were set at 8- to 10-ft. intervals. Later, when the roof span became so wide that the props did not seem to support the roof adequately near the

face, the portable posts were brought into use. The first row of portable posts was placed on 6-ft. centers and 11 ft. from the face, when the wall had retreated 60 ft. from the starting line. Following the next retreat of 6 ft., the depth of a cut, a second row of portable posts was set 3 ft. in advance of the first row. Thereafter, with each retreat equivalent to the depth of one cut, the last row of portable posts was safely moved one at a time to an advanced position.

The retreating wall was cut by an electric cutting machine of the longwall type. This particular machine was replaced some months later by a modern chain machine that undercut as much as 500 tons of coal in  $8\frac{1}{2}$  hr. Shot holes were drilled, 6 ft. deep on 10-ft. centers, with an electric drill, by the use of which two men were enabled to drill and shoot the entire 300-ft. face in 10 hr.

As indicated by the arrows in Fig. 1, the mine cars passed by the face in one direction following the dip from No. 5 entry to No. 4 entry. Under this system, each day one mule could deliver 100 tons of coal from the working face to a side track located about 1,000 ft. away. On the completion of each successive cut the entry track was shortened and the room track was shifted 6 ft. toward the face. Details of the arrangement of the track and roof supports with respect to the face are exhibited in Fig. 2.

No particular difficulty was met in the work, which proceeded as already described, until the wall had re-

## HERE WAS VISION

OVER sixteen years ago Harry S. Gay, Sr., dreamed of loading machines and other means to help perform the work of mining coal. Earlier than that he made use of cutting machines of the chain type and an electric drill. Some of these machines are common now but even today electric drills are used in only a few mines, partly because of union labor's demand for the lion's share of the saving. Experiments in modified longwall systems are being tried in some mines today, of a character not unlike those tried nearly twenty years ago by Mr. Gay.

Fig. 1—Full Retreating Longwall Wouldn't Work Here

An attempt to mine the face A B by this type of longwall method failed because the roof failed to cave as promptly as desired. It was realized that the area of roof unsupported was so great that life would be endangered should any more coal be taken out in that area.

treated a distance of 100 ft. Up to this point in the experiment the roof manifested no tendency to break. It was decided, therefore, to meet the conditions which sometime or other—the sooner the better—would have to be confronted.

So, the track was shifted close to the face, 6 ft. from which 100 portable posts in a single row were set. Then 18 holes were drilled in the roof to a depth of 6 ft. in a line 10 ft. from the posts and charged with dynamite. Twenty of the largest props (not portable posts) were drilled and charged with dynamite for the purpose of lessening the resistance to a fall of roof behind the "breaker row." These charges were fired by hand in quick succession.

A period of waiting followed, in which the roof forces were allowed to spend themselves. An examination revealed the dislodgment of a block of roof having a length of about 100 ft. that had sheared close to the posts on one side and near the opposite rib on the other. The space left by the fall disclosed a bed of strong sand slate without a parting in a thickness of 30 ft. Thus

Fig. 2—Provisions Made to Assure Safety

This scheme was tried when the roof failed to fall as anticipated. The distance between the closest row of posts and the face of the coal was 8 ft. After the face was cut the unsupported roof span was increased to 14 ft. When falls were expected the posts were placed closer to the face.

the examination foretold the difficulties that were to be expected in prosecuting a true longwall system in this seam of coal. Along another portion of the working place the slate broke over the posts and lightly buried 50 ft. of the track. The remaining length—150 ft.—of the roof was undisturbed.

Blasting of the roof reduced the daily tonnage from the face about one-half. The work was continued along the lines described for a period of six weeks following the first fall of roof, during which time it became evident that the method could not be continued with inexperienced labor under the conditions met. A fear was constantly entertained that a mass of rock might break over the posts and endanger the lives of the workmen. At this stage, the experiment was discontinued.

Though Mr. Gay was forced to admit defeat in the pursuance of a system of full retreating longwall mining, because the roof was not stratified sufficiently to break behind the posts, he planned a modification of that system which would retain many of its advantages.

In his first experiment he demonstrated to his own satisfaction that even under the most adverse conditions that he met, the cost of mining was less than that of the room-and-pillar system. Among other factors, the saving was attributed to the

Harry S. Gay, Sr.

Who opened the Gay mine of the Gay Coal & Coke Co. at Logan, W. Va., where he conducted many interesting experiments in longwall mining.

facility with which coal could be moved, the concentration of labor—and that of the less skilled kind—and the simplicity of the ventilation. In a paper describing his early experiments before the Coal Mining Institute of America, Dec. 19, 1906, Mr. Gay gives in the two following paragraphs his conditions and assumptions for his second plan of mining:

"Any method that might be adopted, other than those in vogue in this locality, would have to comply with several conditions: (1) The percentage of coal won must equal on an average that of the other mines in the same coal field. (2) Since all the coal could not be removed by a single operation, pillars of some sort were a natural consequence; therefore, sufficient pillars must be left to sustain the roof for a period of time that would allow each section to be mined in safety. (3) The proportion of narrow to wide work must be such that the additional cost of the former would be absorbed by the decreased cost of the latter.

"The dimensions adopted, which satisfied the three conditions, were based on the following assumptions: (1) Since it was already demonstrated that the roof was self-supporting in a span of 120 ft., it might with perfect safety be worked in a span of 80 ft. (2) If a seam of coal will support 5,000 ft. or more of overlying strata, one-half the coal may therefore sustain 2,500 ft.

of strata, and likewise one-fourth of the coal may sustain 1,250 ft. of strata. Thus 30-ft. pillars, with regular intervening spaces of 80 to 90 ft. between them, might for a time sustain the weight of 1,000 ft. of strata."

The working face in the second experiment was of the same length as that of the first experiment, and was mined in identically the same manner except that pillars were left standing at given intervals behind the retreating block of coal to hold the roof behind the working face. The scheme was thus resolved into a combination of room-and-pillar and longwall mining methods.

Rooms 10 ft. wide on 110-ft. centers were driven transversely into the block of coal, and then widened out to a width of 80 ft., one at a time, in the retreat by slabbing. This left a 30-ft. pillar between each worked-out room. These rooms in reality were sub-entries while the slab cuts differ in no way from those made in the retreating longwall of the first experiment. This layout is shown in Fig. 3.

Trouble with the roof was encountered only near

These rooms were mined in the retreat commencing with No. 12 room which was mined out to a width of 40 ft. before a row of ordinary timber props, of 8- to 10-in. diameter on 15-ft. centers was set as close to the face as the work would permit. When this room attained a width of 50 ft., another row of timber props was set. Thereafter, for each increase of 10 ft. in the width of the room, a row of the portable posts on 10-ft. centers was set and moved ahead as required. The same procedure was followed in working the remaining rooms, one at a time. The action of the roof was manifested to an extent by its effect on the timber props.

As a room approached its maximum width the likelihood of a break in the roof and its inherent dangers increased in proportion; and, therefore, as the room was widened out, greater care in the work and more supervision were required. No subsidence was noted in any of the seven rooms except in No. 12 room, in which the manifestation was only slightly perceptible. The maximum thickness of cover over these rooms was 300 ft.

It was found that 26 men could mine as much as 300

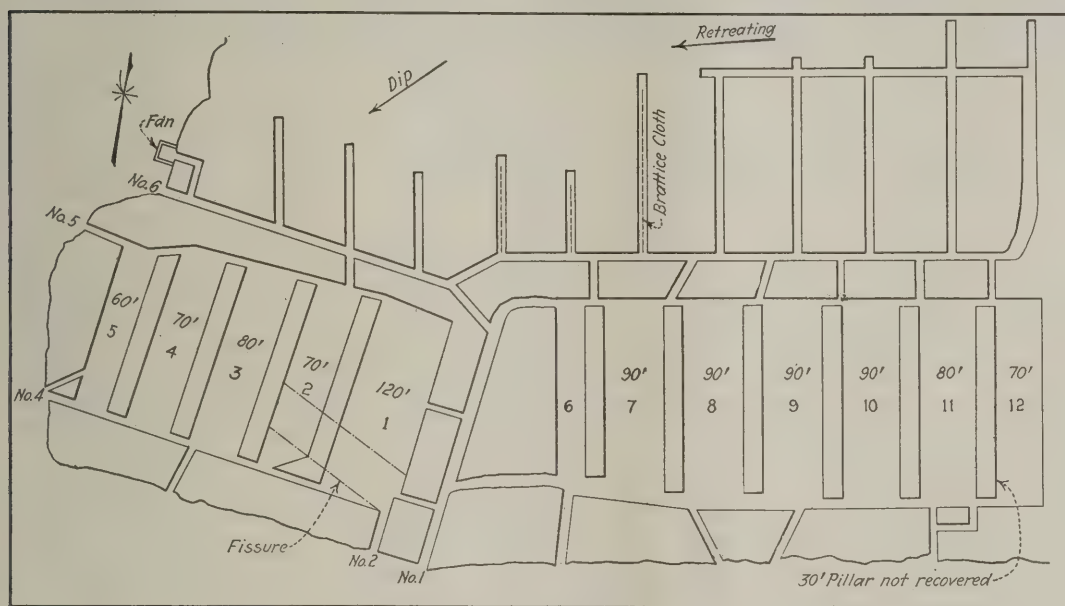

FIG. 3

### Room Slabbing

When the roof hung stubbornly in long spans behind the longwall working face of Fig. 2, 10-ft. places on 110- or 120-ft. centers were driven and the intervening pillars were slabbed, forming 90-ft. rooms, leaving a 30-ft. pillar to hold the roof.

the outcrop, where the rooms were driven as narrow as 60 ft. and auxiliary props were set close to the working face to hold up loose fragments of slate. As a consequence, the details of this plan were believed to meet the requirements of a hypothetical successful system.

At all times the labor worked on solid coal while the pillars left standing and abandoned in the retreat served to stop any general squeeze from spreading any further than the worked-out territory. One objection to the plan was the driving of single narrow rooms into a block of solid coal for a distance of 300 ft., necessitating the hanging of brattice cloth for ventilation in the room being driven.

Freedom from roof trouble under normal conditions in mining out rooms 80 ft. wide led to the belief that the latter could be slabbed to a width of 90 ft., leaving the usual 30-ft. pillar between them. With this object in mind No. 4 and No. 5 entries were driven eastward from No. 1 entry to the boundary line. This development opened up a small panel into which sub-entries were driven from two ends on 120-ft. centers for the widening out of rooms Nos. 6 to 12 inclusive, as may be seen from Fig. 3.

tons per day from one room, and that 12 men could yield an additional 60 tons per day in driving the entries required to maintain adequate development for a uniform output from a room. A total of 39 men mined 360 tons per day, or an average output in the section per inside man per day of 9.2 tons. The average output per man was slightly more or less depending upon the conditions met in mining. At that time in the best of the mines of West Virginia and Pennsylvania using the room-and-pillar system, the average daily output per inside man seldom exceeded 5 tons.

To produce 360 tons from a section, of which 300 tons came from a room and 60 tons from the development of entries, the labor of 39 men was divided as follows:

One Room	Entries
1 Foreman	6 Loaders
2 Machine men	2 Machine men
2 Shotfirers	2 Mule drivers
4 Bottom-scrapers	2 Tracklayers
12 Loaders	
4 Mule drivers	
1 Tracklayer	
1 Timber man	

**Tipple of the Gay Mine as It Appears Today**

On the right can be seen the valley of the Guyan River. The coal (the Island Creek or Cedar Grove) lies high up in the hills 200 ft. above water level among the marvelous woods that have made West Virginia in the matter of scenery one of the most fortunate states in the Union. Each day about 400 tons of slack is dumped on the storage pile and an equal quantity is hauled to a power plant nearby on the right.

Of great interest is a comparison of the results obtained in mining by the true longwall system, described as the first experiment, with those obtained in mining by the system of modified longwall in rooms. A study of the two systems while they were being tried showed that the former yielded a daily tonnage per inside employee 20 per cent higher than did the latter. Had the true longwall system worked successfully it would have permitted close to a 100-per-cent recovery in the Gay mine as against 80 per cent by the modified system. But from the standpoint of safety the modified system showed a decided advantage and, as a consequence, required the services of only a few skilled men.

It is interesting to know that Mr. Gay had an early

dream of mechanical mining. In 1906, before the Coal Mining Institute of America, he remarked, "A mechanical loader is not an impossibility, and the day may come, in some mines, when every division of the work will be performed or greatly assisted by mechanical means, and 10 tons per inside employee will be a regular and steady production."

In a later issue of *Coal Age* an article will appear which describes further modifications of the systems delineated in this article, including the system now being used in the Gay mine. Mr. Gay has tried a number of loading machines, and is now using two with great success. The coming article will deal also with mechanical loading.

**Good Coal Camps Sometimes Have Good Schools**

Here is the new public school at the model coal town of Hiawatha, owned by the United States Fuel Co., in Utah. Twelve teachers are employed using the most modern methods and school equipment to be found in any city educational system. A handsome and comfortable dormitory for teachers, not shown in this picture, helps make life in Hiawatha attractive for these women.

# Mine Locomotives, Their Operation and Control

Why Cable Reels Should Not Be Driven by Locomotive Axles —  
Should Gathering Locomotives Run Fast or Slow? — Difficulties  
with Series-Parallel Controllers—Limitations of Rotary Converters

By F. L. STONE

Industrial Engineering Department, General Electric Co.,  
Schenectady, N. Y.

**F**IRST among the achievements in the use of electricity for the reduction of mining costs was the installation of electric mine locomotives. Long before power companies thought of supplying current to the mines, electric locomotives were busy underground hauling loaded cars from the working face and returning empties. Their power supply usually consisted of small direct-connected engine-driven generator units in sizes up to 300 kw. To compensate for excessive line drop the generators were usually heavily over-compounded.

In this manner the early operators hoped to reduce their expenditure for copper wire. Later experience, however, seems to indicate that it is better practice to maintain as high a voltage as practicable at the substations and make a moderate investment in copper, thereby keeping the voltage up and the energy loss down.

The scheme of wiring and underground transmission varies considerably with local conditions. Sometimes cables are run down the main shaft; in other instances a borehole is put down as close as possible to the center of distribution and a feeder cable dropped through the borehole. Usually, various parts of the mine wiring are sectionalized so that power may be cut off in any part of the mine desired. Since the early days the small engine-driven generators have been dispensed with, and modern substations installed.

The design of the locomotive has changed materially as conditions surrounding its operation have become more thoroughly understood by designing engineers. Mine locomotives may be divided into two general classes, namely: the main-line haulage locomotives and the gathering locomotives; the former, as their name indicates, haul long strings of cars from various central points where the trips are made up.

The gathering locomotive differs from the main-line locomotive in that it is usually lighter, is of shorter wheel base and carries with it a cable reel. The size of the gathering locomotives ordinarily used varies from 3 to 8 tons. The cable reel is usually driven by a torque motor which when the reel is in action is left across the line permanently and thus a continuous torque is exerted on the reel.

One end of the cable is electrically connected to the trolley or other source of power, and when a locomotive enters a room the cable reel is unwound against the torque of the motor. The torque developed by the motor is sufficient to reel up the cable as the locomotive comes out of the room.

Cable reels are built in two distinct forms, one a comparatively long drum of small diameter placed at

one end of the locomotive and the other a large diameter drum with a narrow face, placed on top of the locomotive with its axis vertical. The first requires a mechanical guide to insure the proper coiling of the cable. The short-faced large-diameter reel requires no such device, but, on the other hand, usually adds a few inches to the overall height of the locomotive.

Cable reels of both types were originally mechanically driven from the locomotive axles, but this was found unsatisfactory

because in coming out of a room of any considerable pitch or grade the locomotive runner is likely to lock the wheels. This would stop the cable reel winding in and would allow the locomotive to run over and destroy the cable. Gathering locomotives are usually designed to operate at a speed of from 6 to 7 m.p.h. at the normal rated drawbar pull.

Quite recently operators have questioned whether it would not be better to reduce this speed to approximately 3 or 3½ m.p.h., it being found that few gathering locomotives exceed this speed and that the locomotive runners waste much energy, for they run their motors in parallel with a large quantity of resistance in series. A slow-speed gathering locomotive was designed and installed for one of the large coal companies, and it was found that the daily power consumption was greatly reduced with practically no reduction in the output of coal.

The question naturally suggests itself, why, seeing that most locomotives have two motors and that high speed is obtained by operating the motors in parallel, a series-parallel controller could not be used, which would give practically half speed when operating the motors in series, and also give high speed with motors in parallel when desired. This scheme is entirely feasible and is open to but one criticism, namely, that the locomotive runners will not operate their motors in series but prefer to run in parallel on resistance, notwithstanding all rules and instructions to the contrary.

## ARE GATHERING LOCOMOTIVES DESIGNED TO TRAVEL TOO FAST?

**O**NE company has found that the daily power consumption is greatly reduced and the tonnage not materially lessened by reducing the rated speed of gathering locomotives, for motor-men usually leave much resistance in the circuit, it not being safe or convenient to run in rooms at high speed. The answer to the question is found in the definition of a gathering locomotive. If long runs are made over heading track with short trips or in changing from one gathering center to another, speed is desirable. If the gathering is merely from room to heading the rated speed will not be used.

From a paper on "Electricity in Mines" read at Pacific Coast Convention of the American Institute of Electrical Engineers, Pasadena, Cal., Oct. 13-17. A part of the same paper will be found in last week's issue.

#### Tandem Unit

Where large loads must be hauled some companies use extra heavy single locomotives while others use two moderate-sized units in tandem. There are few, if any, locomotives larger than 20 tons in the anthracite region because here the practice is to use tandem units on stiff grades or long hauls. Single locomotives weighing 30 or more tons are not uncommon in the bituminous coal fields.

The electrical equipment on the gathering locomotives generally consists of two motors totally inclosed and rated on a 75-deg. C. rise full-load one-hour basis. The design of the motor has been materially improved these past few years and today the gathering-locomotive motor operates about as well as any standard industrial motor.

#### ANTI-FRICTION BEARINGS REDUCE BREAKDOWNS

It is equipped with interpoles, and in the better designs has liberally proportioned anti-friction bearings. This latter feature alone has cut down the locomotive repair bill materially. The old-style bearings wore badly, and as the inspection was not of the best, the locomotive would run until its armature struck the pole pieces which usually necessitated a complete rewinding. With anti-friction bearings this complaint is practically unknown.

Most controllers are of the series-parallel type, so well known that no description of them is necessary. Within the past few years, however, one of the large manufacturing companies has built as a standard part of its line a controller of the series-parallel type with an auxiliary cylinder, which, when moved into the proper position, gives the operator complete control of his trip by a dynamic brake action of the motors. This arrangement lightens the manual work of the mine locomotive runner and has proved popular where installed.

The place of the storage-battery locomotive is in my opinion rather limited. Many locomotives of this type have failed mainly because they have been used under conditions for which they were unsuited. Locomotives were put on long hauls that were designed only for short ones. The result was a rapid battery deterioration and consequently heavy renewal charges. I do not mean to indicate by this that the storage-battery locomotive has no field in the mine. In many cases it has a field, but it is not nearly so general as was first anticipated.

Properly designed and operated, the storage-battery mine locomotive has a battery large enough to carry it through a day of normal operating conditions and after an all-night charge is ready for service the following morning. Batteries are usually mounted in a box which is easily removable from the locomotive, so that a new battery can be substituted when desired. The standard speeds of battery locomotives do not exceed 4 m.p.h. at rated drawbar pull. The direct current for charging a storage battery is furnished usually from a motor-generator set installed in the charging room and controlled through a battery-charging panel.

Main-line locomotives are of the same general construction as cable-reel locomotives. Their function as the name indicates is to operate along the main haulageways transporting loaded cars to the foot of the shaft and empties to some central point. In sizes they

#### Gathering Type

Many haulage accidents are due to the manner in which locomotives are maintained—or rather not maintained. The headlight on this locomotive once was new, as also was the controller, which is now half off ready to flash an arc at the motor-man's arm or spit copper into his eyes. Abuse, not use, is the cause for high maintenance costs.

run usually from 6 to 30 tons. The motors are rated on the same basis as the gathering locomotives, and the control is of the series-parallel type.

#### SERIES-PARALLEL CONTROL FOR BATTERY UNITS

One comparatively recent improvement developed for haulage locomotives is the substitution of the ordinary series-parallel controller by a master control and contactors. The main-line currents are handled on contactors of the same general design as those used in street-railway work. Locomotives so equipped have created a favorable impression, and this method of handling main-line currents on contactors in all probability will be adopted by all manufacturers of trolley-type locomotives.

Another important change of design in mine locomotives of all types is in the method of carrying the weight on the axles. Leaf springs with equalizing levers are arranged so that an equal weight is carried on each wheel irrespective of track conditions. This is obviously of great advantage when the locomotive

outdoor or indoor type and is designed along the same lines as similar step-down substations in other industrial work.

Conversion from alternating current to direct current is accomplished either through a motor-generator set or a synchronous converter. If the synchronous converter is used, further transformation of the alternating-current voltage is necessary. If the motor-generator set is used, a motor can be operated directly from the 2,200-volt bus.

#### WHEN TO USE A SYNCHRONOUS CONVERTER

Many engineers fail quite seriously to appreciate the principles which dictate the choice between a motor-generator set and a synchronous converter. At first glance it would seem as though the synchronous converter, because of its higher efficiency, should be used in all places. The determining factor lies largely in the nature of the power supply. If the operator is sure of a constant-voltage supply and does not require any over-compounding of the voltage and is in no need

#### A Go-Getter

There is much questioning in the minds of many men as to the relative values of a trolley locomotive equipped with a cable reel and a battery locomotive. Undoubtedly each has inherent advantages and the only way to make a proper selection is to solve each haulage problem by itself, otherwise one or the other type locomotive may be misapplied.

must travel over rough mine track. In the older types of locomotives when operating on uneven tracks, the weight on the wheels varied greatly, which in turn reacted upon the drawbar pull. The general arrangement of these levers and equalizing devices can be seen in the illustrations.

The larger locomotives are equipped with air brakes and a suitable compressor. The usual motor equipment on modern locomotives is of such capacity as to give approximately 10 hp. per ton of weight on the drivers, the rating being as before stated on a basis of 75 deg. C. rise at rated drawbar pull for one hour.

No practical mine locomotive has been built using alternating-current motors. It, therefore, becomes necessary to provide the locomotives with direct current. Power is delivered to the mines in the form of high-voltage alternating current. This power must be transformed to a suitable voltage and then such of it as is necessary must be converted to direct current for supplying the mine locomotives and mining machines for undercutting the coal.

The step-down transformers are of the usual type transforming the transmission voltage to 2,200 volts. The transformer end of the substation may be of the

of power-factor correction, then the indications point to a synchronous converter.

If, however, the line voltage is variable, any percentage reduction in voltage on the alternating-current side will produce a corresponding reduction on the direct-current side wherever a synchronous converter is used. This reduction in voltage means to the operator a reduction in speed of practically every piece of machinery operating on the direct-current system which reacts in practically the same percentage on his output. If he requires power-factor correction, standard mine motor-generator sets are designed to operate normally at full load with 80 per cent leading power-factor in the synchronous motor.

Synchronous converters cannot be used for power-factor correction beyond operating them at unity power factor. The direct-current voltage of the motor-generator set can be held constant irrespective of the alternating-current voltage fluctuations. The generators of the motor-generator sets can be readily compounded if it is so desired.

The load on a motor-generator set is extremely variable and the set must be built to withstand and commutate satisfactorily 100 per cent overload momen-

tarily and should be capable of carrying 50 per cent overload for 2 hr. without any injurious temperatures resulting.

The control of power-converting apparatus and the units themselves must be capable of withstanding numerous short circuits. One side of the direct-current bus is always grounded. Consequently, the fall

**All Three Motors Do Their Work**

To permit each motor to take its share of the load equalizing members inter-connect the three axles under this unusual locomotive.

of a trolley wire in the mine, which is a frequent occurrence due to faulty roof conditions, will cause a dead short circuit. The control must be capable of removing this short circuit from the generator as quickly as possible.

In large operations it is common to find underground substations working in parallel with stations on the surface. The alternating current supply for these underground stations may be taken down through a borehole or when the proper precautions are taken may be carried through the airway or even through the haulage-way to the substation. The voltage of the direct-current power supply for mines is either approximately 250 volts or 500 volts, the higher voltage installations becoming scarcer as time goes on.

#### SUBSTATIONS NOT SHUT DOWN BY LOAD FAILURE

Many of the modern substations are equipped with full-automatic features exactly the same as many of the railway automatic substations with a possible exception that I know of no mine substation which shuts down on failure of load. This added feature would not be practical in most mines as the load is varying continually in the substation from a maximum to minimum at short intervals of time.

The automatic features, however, which are included are as listed below. These protective features apply to both synchronous converter and motor-generator substations containing one or more units and are arranged to protect against, alternating-current overload, direct-current overload, direct-current reverse power, direct-current reverse polarity, alternating-current undervoltage, loss of motor excitation, loss of generator excitation, single-phase starting, imperfect starting, overheated bearings, overheated windings, and overspeed.

Perhaps the most interesting feature of automatic control is the direct-current breaker which will open on an overload or short circuit and will remain open until the short circuit has been removed, after which it will close automatically. In view of the many short circuits to which substation apparatus is subjected, some few operators have installed what is known as a high-speed circuit breaker.

With the ordinary circuit breaker much time elapses from the time the short circuit occurs until it is stopped

by the circuit breaker, and frequently machines will arc over under this condition. Even if they fail to arc over much burning of the brushes and sparking of the commutator ensues. The high-speed circuit breaker will completely disconnect the machine from the line in less than 0.01 sec. This rapid action prevents the current from rising to any high value beyond the setting of the circuit breaker and consequently it takes the shock of a dead short circuit from the machine.

## European Mines Use Electric Current Less Than We Do

However S. D. Dimmick and H. M. Warren of Glen Alden Coal Co. Learned Something From Them About Tunnel Building and Briquetting

(An interview by R. J. Arthur, Scranton, Pa.)

AMERICAN coal mine operators have little occasion to look to Europe for suggestions on mine electrification. The coal men of Germany, Wales, Belgium and other countries of Europe have not yet overtaken the American producers in the adaptation of electricity to mining methods. Although electricity is used in European mines to perform the same services as in America, its use is restricted and less general. The quantity of electric power consumed by mines abroad cannot begin to compare with the meter readings at American collieries. However, there are interesting things to be learned in Europe's coal mines.

**S. D. Dimmick**

Vice-President and general manager, Glen Alden Coal Co.

The foregoing summarizes the opinion of H. M. Warren, consulting engineer of the Glen Alden Coal Co., who with S. D. Dimmick, vice-president and general manager of the company, recently returned from a tour of inspection of the mines of Wales, Scotland, Belgium and Germany. The anthracite coal company officials found many interesting features at the mining operations abroad and were greatly interested in the various methods of mining, primarily the longwall, which, while not new is seldom used in this country. A study of this method was made with particular reference to the mining of thin seams and many features noted are of particular value in developing methods of mining thin seams in this country. Much other valuable information was obtained.

#### NO ELECTRIFIED TRACKAGE

Throughout the mines on the continent and in Great Britain the visitors found practically no electrified trackage. Rope or chain haulage systems proved to be the most popular, and with these systems the loaded cars were usually moved at a pace not faster than a walk.

The reason for the absence of electrified track in the workings is explained in great part by the system of mining in use abroad—the longwall system—Mr. Warren found. Then again, the cars used for conveying the freshly mined coal are much smaller than those in

use in America, weighing, when loaded, about 1,500 lb. These cars are easily handled by the men in the workings and it would prove a difficult task to demonstrate that electricity would enable the more efficient movement of the cars along the operating face.

In one instance the Welsh operators have adopted electricity in a capacity used in few American mines. It was found in the inspection of one mine in Wales that at the working face the miners are aided in their work by electric lights strung overhead. The lights are moved as the face advances.

A shaking chute installed along the working face for a distance of 450 ft. and pitched at a 10-deg. angle led to the car-loading point. The coal was shoveled into this chute and the forward and backward motion moved it at a fair rate of speed to the waiting car. The chute, as well as the undercutting machine, was operated by electricity. This type of shaking chute is in use in mines in Germany and Belgium, the American visitors later learned.

The electric motor driving the chute was located in the return airway near the upper end of the chute and the coal was undercut by an electric undercutter of the bar type. As explosives are seldom required because of the pressure on the coal, hand picks, and in some mines where the chute and coal cutter are driven by compressed air, picks operated by air are used to bring down the coal.

On the surface, electricity is put to the same use in European mines as in American, but not on as large a scale. In the breakers, washeries and other coal-preparing plants electric power figures prominently. Electric shaft hoists are used quite extensively; pumps, rope haulages inside the mines are electrically operated. However, the use of pumps is not nearly as general as in the American anthracite field. For example, it was learned that European operators pump an average of not over one ton of water to a ton of coal mined, as compared with 11 tons of water to a ton of coal in the Pennsylvania anthracite field.

#### SMALL POWER PLANTS PROVE ADEQUATE

The power plants at the mines abroad, Mr. Warren learned, are as a rule not as large as those producing current for American mining operations. This is due, of course, to the fact that less power is used and small plants prove adequate. At the present time a movement is under way, and is especially indicated in Wales, to consolidate the various individual plants into a chain or power system as is the case with several of the hard coal companies, especially the Glen Alden Co., in this country.

This tendency was regarded by the American visitors as a manifestation of the European operators' growing appreciation of the value of electrified mines.

One of the outstanding features of mining on the continent is the enormous production of briquets, the manufacture of which in the anthracite region in this country has proved more or less of a money-losing proposition. Messrs. Warren and Dimmick saw barge load after barge load of briquets moved through the Rhine district. They were advised that most of it was reparation coal, and was the product of German operators whose methods of production of briquets have met with much success. In France, Italy and Switzerland the visitors noted that large quantities of briquets are used by the railroads, but the general practice is to

H. M. Warren  
Consulting engineer, Glen  
Alden Coal Co.

carry both bituminous coal and briquets on the locomotive tender.

Although several methods of preparing the briquets were in force, one in particular, which is said to be the latest and most improved, attracted the attention of the visitors.

By this system the coal was induced into a long cylinder lined with vanes. The cylinder continually revolved and dropped the coal from top to bottom as it turned. At one end of the cylinder, or kiln, as it is called, the heated binder, usually made of coal tar, was sprayed through the dropping coal by steam and compressed air. This thoroughly mixed the binder and coal and the mixture was drawn out the opposite end and conveyed to the presses. It is claimed by the advocates of this system that from 1½ to 2 per cent less binder is used than with any other method and that a better briquet is produced.

#### NEW METHOD OF LINING TUNNEL

Another interesting development which attracted the attention of the tourists was a new plan of lining a tunnel in deep workings to withstand the enormous pressure which sometimes will crush massive brick tunnel linings. By the new method, which the originator claims to have patented, concrete blocks are used. These were placed in the tubular passageway under construction, but one is omitted every so often in the construction and in its place a wood block is used. The wood block is a cushion relieving some of the pressure and preventing the lining from buckling. Thus far the system has been used with success. It remains to be seen what effect time will have on tunnel linings so constructed.

Economic conditions in the industry abroad were studied to some extent by the American visitors. They concluded that the dormant power of the coal industry in Germany will rise with the re-financing of that country, and with cheaper labor, advanced mining methods, excellent quality coal and lower prices Germany will compete with other European countries for the best markets.

---

WHO WOULD HAVE DREAMED that such a resolution as this ever would be necessary to protect the headquarters—not to mention headquarters and other anatomical divisions of Local 944 United Mine Workers, at the sweet city of Herrin in "bloody Williamson" County, Illinois? "Be it resolved that any member of Local Union No. 944 caught with concealed weapons on him in the hall, shall be fined \$10 for the first offense, \$25 for the second offense and for the third offense shall be expelled three months and fined \$25, the fines to be paid to the man furnishing the evidence. Adopted at a regular meeting, July 8, 1924."

---

MINE VENTILATION seems superior to that below decks in big ships. If the Leviathan hit a rock, for instance, what protection would its vaunted 60,000 cu.ft. of air per minute be against damps?

# Electric Light Plants Contemplating a Plunge Into Gas, Coke and Byproduct Business

National Electric Light Association Is Presented Lengthy Report on Coal Distillation Products—Low-Temperature Carbonization Said to Be Still Commercially Unsuccessful—Gas Making at Mines Suggested

GREATLY significant was the fact that the Prime Movers Committee of the Technical National Section has presented the National Electric Light Association with a report on the Distillation Products of Coal in which articles were contributed by A. G. Christie, V. Z. Caracristi, F. P. Coffin, Arthur D. Little, Inc., and T. C. Keating. Only A. G. Christie's remarks appear in this summary.

Coal men are less awake than the electric light officials to the possibilities of making low-temperature coke and the byproducts that go with it and the advantages, if any there be, of the complete gasification of coal at the mines. It appears that the electric light associations are taking a more fundamental interest in the study of coal treatment than the coal operators themselves. The anthracite region may well interest itself in the activity of the central power stations in planning to make a fuel that will compete with hard coal. An abstract of the report follows:

"Some thirty or more major processes for low-temperature distillation are now in varying stages of development in this and foreign countries. The available information regarding the more important of these has been ably reviewed in the 1923 report of the American Gas Association's committee on Low-Temperature Carbonization and Complete Gasification of Coal. That committee's report summarizes these processes in the statement that:

"There have been no developments along low-temperature lines in this country or in England which would justify any assumption that the art has passed from the experimental into the commercial field. Coal most certainly has not been distilled at low temperatures on a money-making scale, yielding profits sufficient to carry the operating costs and the capital charges. It has been tried experimentally; on a semi-commercial scale, and in one case in a full-sized commercial plant, but it must be recognized that so far none of these attempts has been entirely satisfactory."

"Keen interest has been displayed by various manufacturers in the subject of low-temperature distillation and a disposition to start commercial activity if and when an opportune time in the progress of the art arrives. It seems, however, that on account of its varied nature, the problem lends itself better to commercial solution by ultimate users rather than by equipment manufacturers.

"The determination of the form in which the distillation products will have maximum commercial value continues to occupy the attention of investigators. Much

progress is being made particularly in the use of low-temperature tar oils as a wood preservative. It is now becoming generally conceded that they can be used satisfactorily for this purpose.

"The increasing cost of anthracite fuel for domestic use is proving an incentive to the development of a smokeless fuel made from high-volatile coal. On the other hand, the present low prices of petroleum products act adversely where they determine the price at which certain coal-distillation products can be marketed. The particular incentive in this case is to have a satisfactory process worked out that will be available when higher prices for petroleum products prevail.

"The following statement was received from A. G. Christie, of Johns Hopkins University, as to the present status of coal distillation, and this is embodied in the report:

"Research work on the distillation products of coal during the past year has tended to emphasize more clearly the three fundamental processes that should be kept separately

in mind when discussing distillation. These processes are typified by: (a) Coke ovens, (b) low-temperature gasification, and (c) complete gasification.

"The first process produces a prime quality of coke and also yields about 10,000 cu.ft. of 550-B.t.u. gas per ton of coal, together with 12 gal. of cracked oils and pitch. The second process per ton of coal treated produces about 20 gal. of first-quality oils, about 4,000 cu.ft. of gas with a heating value from 600 to 800 B.t.u. per cubic foot and a coke containing enough volatile matter so that it can be marketed for domestic purposes as a substitute for anthracite. The third process produces the maximum quantity of heat in gaseous form but of varying volume and composition and of low heat value per cubic foot, together with about 20 gal. of oil but no coke.

## COKE OVENS, BAKE OVENS AND GAS PRODUCERS

"The first process is well perfected in the beehive and byproduct coke ovens. The products are well known, and means have been developed to utilize commercially the oils and tars produced and to wash the gases of benzol and other motor fuels.

"The second and third processes are less highly developed, but, because they present interesting possibilities, they are attracting great interest among engineers and inventors. Oils from low-temperature distillation processes proved of great value to Germany during the war as a source of motor fuels and lubricants. Much

COKING process gives prime coke, 10,000 cu. ft. of 550-B.t.u. gas and 12 gal. cracked oils and pitch per ton carbonized. Low-temperature distillation provides a substitute for anthracite, also 4,000 cu. ft. of 600 to 800 B.t.u. gas per ton and oils, mostly of the creosote series and paraffins. Complete gasification gives maximum heat content in gas but of low heat value per cubic foot with about 20 gal. of oil and no coke.

interest is also centered on producing a satisfactory anthracite substitute for domestic purposes. The coke from low-temperature processes offers much promise as it is both smokeless, ignites readily and is comparatively free from dust and dirt. The problem in this country has been to find a way to operate this process at a profit. At present, and for some time to come, it is probable that the price of motor fuels, lubricating oils, etc., derived from crude petroleum will be so low that artificial products from coal distillation will be unable to compete with them on a basis that would offer sufficient financial return to make the process pay.

"American chemists have only started to study intensively these products of distillation and have not yet determined what useful substances may be refined from such oils, or the processes by which they may be produced commercially. It is well to remember that whereas coke-oven oils tend toward the well-known coal tars because the products, to a degree, are cracked in the ovens, the oils from low-temperature distillation tend toward the creosote series and to paraffins. Should the latter process be widely developed, it will be necessary to find a greatly enlarged market for oils of the creosote series. At present prices, it will not pay to attempt to refine paraffin oil from the low-temperature distillation products, although this may be worth while at a later date. The motor fuels derived from washing the gas and distilling the oils are suitable for commercial use and may even now be sold at slightly higher prices than gasoline. The yield of such oils is, however, small with most American coals. It will, therefore, be evident that small commercial returns can be expected at present from the oil products of this process.

"The gas produced has high heating value and would serve satisfactorily for domestic purposes and city distribution. This provides a lucrative market for this product. When high-heat gas is produced, however, heat must be furnished to the retort from some outside source. In certain cases, producer gas has been proposed for this purpose. This lessens the efficiency of the process.

#### SEMI-COKE MADE TO SUPPLEMENT ANTHRACITE

"Evidently it is to the resultant coke of the low-temperature distillation process that one must look for financial returns to justify the process. The ever-increasing price of anthracite in the East and the increasing smoke nuisance in the Middle West is steadily adding to the commercial possibilities of the process, and it is probable that it will be rapidly developed, its primary object being the substitution of this coke for other domestic fuels.

"The third process has been developed in many forms. The bituminous gas producer, so largely used in the steel industry, and the water gas sets used in making illuminating gas are too well known to require description. The primary object in each case is the complete gasification of the fuel and any tars that may result are generally regarded as unavoidable losses incident to the process.

"The two processes of complete gasification just

mentioned have been made the basis of some of the newer developments. The Mond process, for instance, uses steam in the entering air to keep it down to producer temperature, so that a modified form of low-temperature distillation takes place. Others have gone further and have actually combined low-temperature distillation with the water-gas process as in the Strache system. A plant at Bologna, Italy, built on Strache patents operated satisfactorily for some time on Fairmont, W. Va., coal. These modified processes besides yielding

large volumes of low-temperature distillation oils, also produced gas of higher heating value than that made in producers. Stache claims that the gas has a heating value of 300 to 400 B.t.u. per cubic foot. Later processes of higher efficiency are being developed which combine the Mond process with the low-temperature distillation method, and these later developments appear quite promising.

"In this country the Carbocoal process is operated primarily as a low-temperature distillation system to produce substitutes for anthracite. The Piron process, now being developed, apparently has the same object in view. The Bussey process, has the same purpose, namely, the production of a smokeless domestic fuel from soft coal. It achieves this result by allowing a portion of the coke formed to burn to producer gas which in rising through the retort distills off the low-temperature oils. The resultant gas is, therefore, much leaner than that from the two preceding processes.

#### CAREFUL STUDY GIVEN TO SUBJECT IN BRITAIN

"American engineers are not alone in their interest in low-temperature carbonization methods. The subject is being given close study in Great Britain, where the government has carried out some extensive research work on which reports have been issued from time to time.

"At present the public-utility engineer has little interest in these processes unless he has charge of a gas plant as well as an electrical station. This condition, however, may change rapidly, for there are possibilities in these new processes that may prove of consequence to central-station men. Increasing demand for a smokeless fuel may make it advisable for certain central-station companies to organize subsidiary concerns for the purpose of producing such fuel. The byproduct gas, if of high heat value, may be turned over to the local gas company or sold to manufacturers if of low grade, or it may even be burned under the boilers of the central station. Waste fuels such as coke breeze and dust may be burned efficiently under boilers. Combining the byproduct plant with the central station would lessen coal storage and unloading expense and would afford the gas plant a means of getting rid of waste products.

"A still more interesting possibility is the transmission of fuel from mine to central station by means of gas pipe lines. The increasing freight rates on coal and the improvements being made in the efficiency of several gasification processes raise the question as to the advisability of converting all fuel into gas, oils and ash at the mine mouth transporting only the gas to

the point of consumption. This is a particularly pertinent question where near-by low-grade coals are used as in certain places in the Middle West and where such coals may run 30 per cent or more of total moisture and ash.

#### GAS SYSTEM AIDS PLANT EFFICIENCY

"It does not seem economic to pay freight on this waste material as well as handling charges on the coal and ash at the central station. Gasification at the mine would relieve the central station of its ash disposal problem. The elimination of coal bunkers, coal preparation and handling equipment, stokers, ash bins and ash-handling equipment, soot blowers, dust catchers, etc., would lessen the investment in the power station, though this might be offset by an investment in reserve gas holders. Power-plant operation would be simplified if gas were employed as fuel, and labor charges would be reduced. No smoke would be produced, which, alone, is a consideration of appreciable value. Furthermore, the use of gas should make higher plant efficiency possible.

"Many factors, therefore, favor this system. All of them would have to be considered as well as the fixed charges and operating costs on the gas plant and pipe lines, together with the commercial value of the oils produced before a correct valuation could be made of this system. This problem will demand the attention of engineers in the near future and hence the importance of following closely all developments in the low-temperature carbonization and complete gasification of coal."

### Southern Rhodesia Has Seven Billion Tons Of Good Coal 20 to 46 Ft. Thick

AN ESTIMATE of the coal of economic value in Southern Rhodesia contained in seams of workable thickness, situated within mineable distance from the surface and which is said to be quite conservative is 969,411,000 metric tons, according to H. B. Maufe, in a paper read before the World Power Conference. This statement is based on the 1914 report of the Rhodesian Geological Survey. Subsequent exploratory work, says Mr. Maufe, especially in the Wankie coal fields has shown that the estimate is more than safe. The Wankie main coal has been found to be 28 to 30 ft. thick over a large area, and over a smaller area its thickness is 46 ft. The explored area of the Wankie field is perhaps 300 square miles and if the thickness is estimated at only 20 ft., the reserve of coal may be written in round numbers at 6,434,000,000 long tons. Later exploration in the Sebungwe coal fields permits us to increase the 1914 estimate to 300,000,000 tons. In the Sabi and Tuli coal fields, as no new information has come to hand, the figure remains at 80,000,000 long tons.

#### DEPOSITS ALMOST EXCLUSIVELY SEMI-BITUMINOUS

Thus the coal resources of Southern Rhodesia may be put at 6,814,000,000 long tons. In the 1914 estimate it was shown that 85 per cent of the coal was semi-bituminous, suitable for steam raising, and the other 15 per cent was in part bituminous and in part semi-anthracite. The more recent additions to the resources have increased the percentage of steam coal which may now be put at 98 per cent of the total resources.

From eighty-eight samples taken from the Wankie

colliery, the only producing coal mine, the following average analysis has been obtained: Moisture, 0.76 per cent; volatile matter, 23.77; fixed carbon, 65.70; ash, 9.77. The British thermal units obtained on combustion number 13,433 and the evaporative power is 13.89 lb. of water per pound of coal. At the New Colliery shaft, two samples gave 14,004 and 13,912 B.t.u., the ash being only 7.02 and 7.75 per cent respectively in these two samples.

### Steel Buildings Outlast Those of Wood

SURFACE buildings, fabricated of steel, and made sectional so as to facilitate easy assembly, are coming into favor at many coal mines. Their advantage is not restricted to low first-cost, for they possess other merits of almost equal importance. Mine owners who have erected them in place of buildings constructed of more massive materials assert that the objections raised to lightly-constructed buildings do not apply to the type made entirely of steel.

Fabricated buildings are permanent in the sense that they will outlast any ordinary mine, providing they

A Fabricated Shop in West Virginia

This building is 45 x 75 ft. in plan or plenty large enough to accommodate the electrical and mechanical departments necessary to the production of 1,000 tons of coal per day. Not only can such buildings be erected quickly but if placed on suitable foundations, and kept drained and painted they will last indefinitely.

are amply supported on good foundations, are painted periodically and are properly drained. Such buildings are so well proportioned that drafts are eliminated, there being no wide cracks between adjacent sections. As the superstructure is composed of steel members and the siding is of the same material, fire represents no hazard. Windows and doors can be located wherever they will serve their purpose most effectively. The ultimate salvage value, the portability of the fabricated building, as well as its convenient construction which allows additions to be made at any time without interfering with current operations, are no more striking advantages than the constructional details which enable such a building to be erected in a small fraction of the time required for the building of a brick or other "permanent" structure.

SINCE LONDON'S 4,500,000 people use less generated power than St. Louis' 1,000,000, there is an irresistible chance for the admiring Irish to say the English have strong backs but weak minds.

COAL MEASURES in Congress are often more gaseous than coal measures in the ground.

# How to Make Preparations Against a Fire or an Explosion and What to Do When It Occurs

Statistics Based on 164 Disasters of This Kind as Studied by Engineers of  
Bureau of Mines—Five Hundred Lives Saved by Fan Reversal  
—No Lives Lost by Reversing Fans

By D. HARRINGTON<sup>1</sup> AND M. W. VON BERNEWITZ<sup>2</sup>

**I**N STUDYING the mine-disaster files of the U. S. Bureau of Mines for preparation of a bulletin<sup>3</sup> on coal-mine explosions, a table was compiled covering various features of fan installation and the handling of air currents at the time of and after the disasters. As a sidelight on this discussion the loss of life and number of men injured also was tabulated.

Of the 164 disasters tabulated, 143 were explosions, 14 were fires, and 2 involved both fire and explosion. The total loss of life was 4,158 and 412 men were injured. One hundred and forty-five disasters occurred in bituminous-coal mines, 13 in anthracite mines, 2 in lignite mines, 1 in a cannel-coal mine and 3 in metal mines. By states, 35 took place in Pennsylvania, 17 in West Virginia, 16 each in Oklahoma and Alabama, 15 each in Kansas and Illinois, 12 in Indiana, 7 in Colorado, 6 in Kentucky, 3 each in Ohio, Tennessee and Wyoming; 2 each in Arkansas, Montana, Washington, Virginia, New Mexico and Utah and 1 each in Iowa, Missouri, Maryland and California.

The fans at 47 of the mines were steam-driven, 36 were driven by electricity, 4 by either steam or electricity, 2 by gas and one by either gas or electricity. Information is lacking as to the method of driving the fans at the remaining 75 of the total of 164 mines tabulated. As to the method of ventilating, 103 fans were operated exhausting and 64 were blower or pressure fans. In 42 instances the fans were equipped for quick reversal of the air current in case of necessity and 19 were non-reversible. Information is lacking as to the reversibility of the fans at the remaining mines. Some mines, especially in the anthracite region, have several fans. The capacities of single fans varied up to 350,000 cu.ft. per minute.

## LIFE OFTEN SAVED BY REVERSING AIR CURRENT

Immediately following ten of these disasters the air currents were reversed by use of the fan. This in five cases resulted in a saving of life, the number of lives preserved totaling more than 500. In one instance prompt reversal of the air currents by the mine officials after an explosion saved about eighty lives. In another and comparatively recent instance (1924) the direction of the air was promptly reversed by manipulation at the fan at the time of a mine fire, and over twenty lives were saved. In still another case, at the time of a coal-mine fire, through ability to reverse the air currents promptly, numerous lives were saved, and the reversibility of the fan was utilized frequently in fighting the fire. At least once, and probably in two

instances, reversal of the air drew methane over fires and explosions occurred, but without loss of life.

In the above list, which includes most of the major disasters that have occurred in the United States since 1907, there is not a single instance of loss of life having occurred directly or indirectly as the result of reversal

Here Two Fans and Two Steam Lines Guarantee Continuous Ventilation

The photograph from which this picture was made was taken at Zeigler, Ill. Each line has two loops to provide for expansion.

of the direction of air currents by fan manipulation. However, in a number of instances in recent years there has been loss of life due to reversal of air by a fire, there being no fan available to control the direction of the ventilating current. In some instances there undoubtedly has been loss of life because the fan was non-reversible and a reversal of air currents could not be effected without serious loss of time.

An incident at one mine is worth recording, as being a detail worth watching: At the time of the explosion the explosion doors on the fan housing opened and thus saved the fan from injury, but by some means the reversing door was forced halfway over the air duct and remained jammed until it was discovered and moved back.

In at least two cases after the fan was put out of commission by explosions a reserve fan was used. In

<sup>1</sup>Formerly mining engineer, U. S. Bureau of Mines.

<sup>3</sup>Von Berenwitz, M. W.; Rice, G. S., and Paul, J. W.; Causes of and Lessons from 200 Coal-Mine Explosions, Bull. 237, U. S. Bureau of Mines (in preparation).

at least one instance, also, many lives (probably more than 100) were undoubtedly saved by having a reserve fan ready for use. In one case at the time of a disaster the fan was stopped, and the methane that accumulated came in contact with burning feeders and caused an explosion. In one coal mine an underground fan was driven by a gas engine, and when a fire started the gas tank exploded and thirteen men lost their lives. In another instance in a metal mine a fire started underground at the motor of an electrically driven fan and twenty-one lives were lost. In connection with this latter disaster it may be stated that during recent years many fires in metal mines have been started by electric motors serving underground fan installations, these being chiefly small temporary units for the ventilation of blind ends where tubing is used to carry the air to the face.

#### HIGH-SPEED ELECTRICALLY DRIVEN FANS FAVORED

Modern practice at coal mines seems to favor electrically driven high-speed fans in fireproof housings on the surface, and although such fans usually are operated exhausting they are equipped with doors, so that, if necessary, the air currents may be quickly reversed. Many up-to-date properties are fitted with a second or auxiliary fan, or at least a second source of power for the fan drive. One successful installation of this kind is located in Alabama. At this plant when the electric power for the fan was cut off by an explosion a kerosene engine with a jaw-clutch attachment to the fan shaft was put into commission within 15 minutes with practically no interruption of air circulation, thus saving many lives. Here an ingenious small-capacity compressed-air installation allowed almost immediate starting of the kerosene engine. Frequently there is much delay and difficulty in starting gas engines that at best are used only occasionally.

Present-day practice at coal mines demands that the fan be installed well out of direct line with the air-course leading to it. It also should be provided with suitable outward opening and easily operated doors in the direct line to allow of quick relief of pressure in case of explosion, thus protecting the fan from the explosive force. The record shows that in at least eight instances the relief doors operated and saved the fans. In two severe explosions during the past few years the fan approach purposely was made of flimsy material, yet kept tight by means of gunite. This

saved the fan by readily collapsing, and mine ventilation in each case was readily restored within an hour by temporary repairs.

In ventilating installations at metal mines the main fan frequently is placed underground. This is a practice that would not be tolerated in coal mines. It entails positive dangers in metal mines, though undoubtedly it is advisable in some cases. Exhaust fans predominate at coal mines and are fairly common at metal operations. They draw the ventilating current from airshafts, thus making the hoisting shafts downcasts. Pressure fans also are common at metal mines, and there are good reasons for both practices.

#### EXHAUST FANS PREFERRED AT COAL MINES

At metal mines it frequently is necessary to force back into the surrounding workings heated air or gas issuing from the adjacent strata or from timber. To do this it is advisable to maintain the air in working places under slightly increased pressure. On the other hand, it seems advisable to pull (exhaust) as much as possible of the methane, the principal gas found in coal mines, out of the worked-out or abandoned sections and into the circulating air so as to render it non-explosive. Moreover, it is felt that should the methane in coal mines be forced back into the goaf, or into abandoned sections by pressure ventilation (hence by extra air pressure within the mine), as soon as there is any relief of that pressure, such as might result from a change of barometer or slight or total interruption to air circulation, excessive quantities of gas would be released as a result of the decreased pressure. This would be dangerous. However, some coal mines use pressure ventilation, and some metal mines employ the exhaust system.

In one metal-mining district where many of the principal fans were blowers, causing the main haulage and travelway to be the return aircourse in time of fire, the gases cut off the travelway. Later on, however, the main fans of this district were changed to exhaust units, with intake on the main haulage and travelway.

Though hazardous in any mine, the placing of small fans (boosters) underground to assist in air distribution is dangerous and inefficient in coal operations, yet this is considered good practice in metal mines. In any underground fan installation the adjacent workings should be thoroughly fireproofed, even though the fan is but temporarily in any one position. In coal mines

#### Fan Installation

At an Illinois mine. To the right is an auxiliary hoist. The curved duct on the right connects the fan-way with the shaft. Arrangements should be made here so that an explosion would open a door or break out a portion of the curved duct so as to save the fan from violence.

### At Baker Breaker

Fan installation of the Glen Alden Coal Co., near Scranton, Pa., with an *evase* discharge opening. Modern fan houses are made of permanent construction, for the fans are the lungs of the mine. This is normally an electrically driven fan, but the piping shows that steam power also is provided.

the greatest possible care should be taken against ignition of methane at fans by short-circuiting either after fan stoppage or otherwise. Such ignitions are liable to cause great damage.

There is a diversity of opinion as to what should be done at the fan in time of disaster. As a matter of fact no set rule can be given, except that if damaged by the explosion or fire, the fan should be placed in running order immediately. All mines, whether coal or metal, should have the ventilating system arranged so that the direction of air travel may be controlled at the fan; then in case of necessity the direction of the air currents may be reversed within a few minutes. No change should be made in the usual coursing of air unless available information indicates that advantage may be gained either by stopping the fan or by reversing the air.

Many mining men advocate stopping the fan immediately upon learning of trouble underground. This may be good policy in some instances, but there are others in which it would certainly result in disaster. In the first place, merely stopping the fan does not insure that the air currents will stop, and if it is desired to stop the air flow, other definite steps, such as placing brattices or the opening or closing of doors, are necessary. Moreover, even if the air circulation is stopped at or near the fan, an underground fire quickly establishes its own circulation, and especially if the mine is gaseous there is grave danger of an explosion as the result of a local circulation of methane accumulations (arising from fan stoppage) over fires, ignited gas blowers, etc.

#### FIRE MAY REVERSE AIR CURRENT DIRECTION

Again, in case of a mine fire the fumes will have been carried through the mine in the usual direction of air flow until the fan is stopped. Frequently upon stoppage of the fan the fire reverses the direction of air movement, and thus fills the remainder of the mine with deadly gases. Reversal of direction of the air at or near the fan will not necessarily cause change of direction of air currents in the interior of the mine, unless provision has been made to hold doors closed, even where pressure against them becomes suction, or *vice versa*. Hence to make air-reversing installations at mine fans effective they should be tested at intervals to determine their probable efficiency in case of emer-

gency, and immediate action should be taken to remedy defects shown by the trial.

Observations by U. S. Bureau of Mines engineers after disasters indicate that underground workmen are prone in time of disaster to try to follow accustomed travel routes irrespective of their condition as regards falls, gases, etc. Consequently about as good a general practice as can be followed is to try to supply fresh air to the usual travelingways, so far as this can be done by causing the fan to continue to circulate air in them either in the usual or in a reverse direction. In order to accomplish this latter operation it is obviously desirable to have the fan installation of such a nature that reversal may be accomplished with minimum loss of time. On the other hand, it is equally obvious that no change should be made in the usual coursing of the mine air currents except under orders from a responsible mine official who has carefully considered the various phases of the existing conditions.

### Bituloid Adversely Discussed at Cardiff

When the South Wales Institute of Engineers met, Oct. 16, at Cardiff to discuss the paper of Prof. Henry Briggs and Norman H. Walls on the use of Bituloid, an emulsion of tar, as a means of allaying dust and preventing mine explosions (a paper that was briefed in the issue of *Coal Age* of Oct. 30), Guy de G. Warren declared that despite the fact that Bituloid had the desirable quality of oozing and so could soak up into new dust when it would fall onto any Bituloided surface, it could not be assumed that this ability to ooze would be maintained indefinitely.

In time the settling dust would no longer adhere and then a dangerous condition would be established, Mr. Warren declared that if, as the authors of the paper stated, a periodic cleaning up was desirable it would be found probably that the men engaged to do the work would long for the incombustible dust, feeling that it was a much easier and pleasanter material to remove from floor, roof and sides than a tacky substance like Bituloided mine dust that stuck to everything it touched.

J. W. Hutchison in expressing his approval of shale dust wanted to know how the authors of the paper proposed to deal with an accumulation of dust and Bituloid on heavy timbers.

## News Of the Industry

### Central Pennsylvania Operators Again Ask Readjustment of Union Agreement

Letter to Brophy Says Predicted Prosperity Has Not Materialized—  
District's Output Falls Behind Former Years—Increasing  
Business Going to Non-Union Fields

Readjustment of wages and working conditions is asked in a letter sent Nov. 7 by the Association of Bituminous Coal Operators of Central Pennsylvania, with headquarters at Altoona, Pa., to the United Mine Workers, District No. 2. The operators' letter, which was signed by B. M. Clark, president; G. Webb Shillingford, vice-president, and Charles O'Neill, secretary, was addressed to John Brophy, president of District No. 2, but requests an answer from the District Executive Board. The communication, in part, was as follows.

"In the recent past a number of statements were made public by representatives of the coal operators' association, which may be summarized as follows:

"The diminishing coal business in central Pennsylvania is caused partly by the general industrial depression under which all coal operators and other business men suffer, but principally by our unfavorable competitive position due to high cost of production in this district compared with a low cost of production in competitive districts. The high cost of production is due, of course, to the union wage scale, which is much higher than the wage schedules in effect in the non-union sections which are competitive with us.

"Two hundred millions of tons of the coal accessible to the Eastern markets and competitive with our coal is being produced from 50c. to one dollar per ton lower cost than coal can be produced in our district under the union wage scale."

#### Quote Miners' Statement

"The statement on behalf of the United Mine Workers said in part:

"Coal production has been at the lowest level in years. Consumers are not buying coal. Operators are not able to sell coal at any price because consumers do not want coal and will not buy it until they need it. Coal prices are now down to the lowest point in many years; still there is very little market.

"The reason for the operators' frantic efforts to set aside the present contract is obvious to anyone who cares to look into the matter. They are seeking to bring about a wage reduction when business is poor so that when business improves and they are

able to sell their coal they will make larger profits by reason of the reduction in wages to their employees."

"The joint wage agreements between miners and operators have been continuous since 1899 except during short periods of strike in 1906, 1919 and 1922. In all of this time and in all of these agreements the operators have never had wages reduced during the life of an agreement.

"In 1909 the operators asked for relief and were denied by the Mine Workers upon the ground that the agreement was binding and would not be changed.

"Five times in three years, however, agreements have been changed in favor of the miners to meet conditions as they developed during the period of the life of the agreement. The agreement was not ironclad when increases were being forced from the operators.

#### Conditions Alarm Operators

"The present situation in central Pennsylvania justifies the grave concern shown by owners of mine properties and the anxiety indicated by the business men and citizens of our communities. For the week ending Oct. 18 the country produced 10,255,000 tons. This is a large tonnage and equal to the average for this period of the year. A few weeks ago we were producing between six and seven millions of tons weekly. The seasonal demand for coal due to approaching winter is here. Your prediction of prosperity to central Pennsylvania has failed to materialize. The increased business has gone to other fields.

"During the five-year period from 1916 to 1920, inclusive, we mined 10.5 per cent of the total, or over 1,000,000 tons per week. To-day we are actually mining about 800,000 tons per week.

"The country has produced from Jan. 1 to Oct. 18, 1924, 363,156,000 tons. Had central Pennsylvania maintained its position it would have produced 38,131,380 tons. Instead we have produced but 30,670,782 tons, or have lost to other fields 7,460,598 tons of our share of the country's business. Of 40,882,000 tons produced in the country for September, our district produced only 3,297,135 tons, or a loss for this month of 995,475 tons. The increase in business is going to the non-union fields.

"We have waited for the return of the 'prosperity' predicted by you. We are now convinced that it is not forthcoming. Due to the winter demand for coal the production in the country has increased to well over 10,000,000 tons per week. The increased tonnage of coal has been produced in the non-union fields rather than in the union fields. Central Pennsylvania's position as a producer of coal remains practically the same today as it was when the country was producing but 7,000,000 tons per week. This loss of production to central Pennsylvania is due to the high cost of production in our district under the present wage scale. Our competitors have a much lower wage scale, hence are securing the business.

#### Place Blame on Union

"The responsibility for the further strangulation of the coal business rests with your organization. It can be seen in the idle mines, in the desolate towns, and in the migration of hundreds and hundreds of union miners to other industries and non-union fields.

"We speak with frankness and expect action upon your part based upon reason and a desire to co-operate in the successful conduct of the industry. When conditions during the period of an agreement required changing to meet the necessities of your people, the operators of central Pennsylvania have granted you concessions in increased wages. We believe that in relieving such situations upon your requests and upon your demands during a period when you were bound to work for an extended period of time upon a fixed and lower wage scale than we conceded to you during such period, it fixes upon the United Mine Workers a responsibility to recognize the present condition in our industry and to help restore central Pennsylvania to her proper place as a producer of coal.

"We respectfully suggest that this year's business for the union miner and union operator is closed. Coal contracts have been made for the year's business. Spot market winter supply has been provided. Do you want to carry the present year's experience into another year's business of the industry in central Pennsylvania? What suggestions have you to make to relieve the union miner, the union coal operator and the business interests of the communities in which we reside, and to secure their future happiness and prosperity? This communication has been simultaneously submitted to you and the press because of the deep interest the public has manifested in the present condition.

"We respectfully request a reply from your district executive body to this communication."

## Speculation on Cabinet Elicits Mention of Lewis As Secretary of Labor

Great interest is being manifested in Washington in the action which President Coolidge may take in connection with the Interior portfolio. This department of the federal government has been much in the limelight during the past two years. Its reorganization along lines which would require legislation has been urged strongly, but the legislation has not been forthcoming. Some are of the opinion that the effectiveness of the department can be increased greatly without legislation through internal reorganization. In that connection the suggestion has been made that this reorganization should be entrusted to Herbert Hoover. It is argued that he has reorganized the Department of Commerce and has it running so smoothly that its direction relatively has become a matter of routine.

Despite all of the speculation which is going the rounds, it is probable that the President is giving little thought to the personnel of the new Cabinet. It is recognized as one of the most disagreeable tasks which a President must perform. It is not unusual for literally hundreds of names to be suggested for each position. Only one can be chosen, which usually results in disappointment and ill-feeling on the part of many of the friends of the others.

In so far as the Interior Department is concerned there is no definite information as to the desire of Dr. Work to continue and no intimation has come from the White House that a change will be made. The name of Frank W. Mondell has been mentioned for this place. He is one of the wheel-horses of the Republican party, but the probabilities are that his conception of conservation would preclude his selection for that post.

An appointment is expected in the near future to fill the vacancy created by the death of Secretary Wallace. President Coolidge departed somewhat from custom when he asked the farm organizations to submit indorsements for the agricultural ministry. As this is written the President has before him thirty names. Each day is expected to see a lengthening of the list.

All agree that Secretaries Hughes, Mellon, Hoover and Stone will be urged to remain in the Cabinet. There is reason to believe, however, that Mr. Hughes and Mr. Stone would like to resume their law practices. The probabilities indicate, however, that their retirement will not come on March 4, although they may not serve out the full four years of the coming term. Secretary Hoover is known to have determined to devote the remainder of his life to public service. It is generally believed in Washington that he will continue in the Cabinet. Secretary Mellon is not the type that is impervious to the flood of attacks of a political and frequently of a demagogic character. Many of the thrusts in his direction got beneath the skin. His tax plan was defeated and many think it

Senator F. M. Sackett

Kentucky elected a real coal man last week as U. S. Senator for the next four years, when Fred M. Sackett, of the Sackett-Speed interests, of Louisville, defeated Senator A. O. Stanley by about 20,000 votes. The Sackett-Speed interests operate three big mines in eastern Kentucky and one in western Kentucky, also the Byrne & Speed Coal Corporation, retailers and jobbers, of Louisville. Mr. Sackett, who is about 55 years of age, was born in Providence, R. I. He studied law and practiced at Columbus, Ohio, Cincinnati, and later at Louisville, where he became president of the Louisville Gas Co., now a part of the Louisville Gas & Electric Co., one of the Byllesby interests. He has served three terms as president of the Louisville Board of Trade.

will be defeated again if it is presented to the new Congress. This, along with the fact that he is not a robust man, is expected to cause him to retire.

There is much talk of John L. Lewis as a possible selection for the secretaryship of labor. Since the Secretary of Labor is the representatives of all labor, union and non-union, some objection might come from workers outside the union as to the ability of Mr. Lewis to be their real friend at court.

Secretary Weeks has done such a good job in the War Department and it is so evident that he is happy in this work that a change in that department is thought to be very unlikely. Secretary Wilbur is the President's own choice. He was induced to leave the bench of the Supreme Court of California to take the navy secretaryship. It is not likely that he will be changed unless a judicial post should open which appeals more to him.

A change of Postmaster General is expected by many.

## Third Kanawha Company Signs Union Pact

The Bib Bottom Coal Co., which operates on Campbell's Creek in the Kanawha field of West Virginia, has signed an agreement with the union. The company expects to resume operations immediately. The Bib Bottom company is the third company in the Kanawha field to sign the union agreement since the mines which formerly had been working on a union basis in the Kanawha field closed down on April 1.

## Atwater Obtains Control of Mill Creek Company

Wm. C. Atwater, president of Wm. C. Atwater & Co., 1 Broadway, New York City, has confirmed the report that he has acquired the Cooper interests of 60 per cent of the capital stock of the Mill Creek Coal & Coke Co., located at Coopers, McDowell County, W. Va., in the heart of the Pocahontas field. The Mill Creek company has an annual output of a quarter of a million tons. The reported price paid for this interest is \$3,000,000. Mr. Atwater already controls the American Coal Co., the Elkhorn Coal & Coke Co., the Fall River Coal Co. and the Williams Coal Co., all located in the Pocahontas district, and with the purchase of the Mill Creek company he becomes one of the controlling factors in the smokeless fields of West Virginia.

The Mill Creek Coal & Coke Co. is one of the few companies in the Pocahontas field that still makes coke in beehive ovens and there are fifty-five ovens on the property that have burned coke continuously for thirty-six years. This mine was the first mine to ship coal in the West Virginia side of the Pocahontas district. There are eight million tons of coal 9 ft. thick left in the property to be mined out.

Mill Creek mines were opened up by the late John Cooper forty years ago and the first carload of coal was shipped Nov. 4, 1884, the day that Grover Cleveland was first elected President of the United States. Mr. Atwater can well remember Mr. Cooper telling him twenty-five years ago of his shipping the car of coal and then together with the late Jenkin Jones, another old pioneer operator in the Pocahontas district, riding horseback to Princeton, the county seat, to vote and when they called for a Republican ballot found there was none to be had.

Mr. Atwater is president of the Pocahontas Operators Association and is regarded by business associates as one of the most progressive coal operators in the country. He became president of the Mill Creek company on Tuesday.

## Fuel Consumption and Power Output by Utilities Up

Electric public utility plants consumed 3,010,901 net tons of coal during September, according to a report by the U. S. Geological Survey. This compares with 3,015,797 tons consumed in August, according to revised figures. Fuel oil consumed by utility plants during September totaled 1,389,780 barrels, compared with 1,498,769 barrels consumed in August. As September was a 30-day month the daily consumption was greater in the latter month, despite the larger totals for August.

The average daily production of electricity by public-utility power plants during September was 160,200,000 kw.-hr., which is almost 5 per cent greater than the daily output during August and 6 per cent greater than for September a year ago.

## Inspection Tour of Magnates Deepens Interest in Hard-Coal Merger

Twenty Industrial and Financial Leaders Guests of Hudson and Glen Alden Officials at Marvine and Baker Breakers—Only an Educational Trip, Says Loree

A score of the country's foremost business and industrial leaders, including railroad presidents, bank presidents, captains of industry and financial magnates, all of whom are members of the National Industrial Conference Board, were in Scranton, Pa., last Friday, when they inspected the Baker breaker of the Glen Alden Coal Co. and the Marvine breaker of the Hudson Coal Co., the most modern preparation plants in the anthracite field.

The visit occasioned much comment in view of the reports of a contemplated merger of big coal producing-companies, including the Glen Alden, Erie (Pennsylvania) and Hudson Coal Co. properties. On the surface, however, the visit had no bearing on such a move. It was merely a semi-pleasure and educational trip, or as L. F. Loree, president of the Delaware & Hudson railroad, stated, "A sort of Rotary Club educational trip."

### Financial Leaders in the Party

The party included the following: Edward F. Loomis, New York City, president of the Lehigh Valley R.R.; L. F. Loree, New York City, president of the Delaware & Hudson R.R.; J. T. Loree, Albany, N. Y., vice-president of the Delaware & Hudson R.R.; S. D. Warriner, Philadelphia, president of the Lehigh Coal & Navigation Co.; William H. Williams, New York City, vice-president of the Hudson Coal Co.; Walter E. Frew, New York City, president of the Corn Exchange Bank; Loyall A. Osborne, New York City, president of the Westinghouse International Electric Co.; Herman H. Westinghouse, New York City, chairman of the Westinghouse Air Brake Co.; George M. Verity, Middletown, Ohio, president of the American Rolling Mill Co.; Guy E. Tripp, New York City, chairman of the Westinghouse Electric & Mfg. Co.; William H. Nichols, New York City, chairman of the Allied Chemical & Dye Corporation; William H. Nichols, Jr., New York City, president of the General Chemical Co.; Herbert F. Perkins, Chicago, Ill., first vice-president of the International Harvester Co.; Herbert H. Rice, Detroit, Mich., president of the Cadillac Motor Car Co.; Dr. John J. Moorhead, New York City, professor of surgery, Post-Graduate Medical School and Hospital; A. H. Harris, New York City, chairman finance committee and vice-president of the New York Central R.R.; John Henry Hammond, New York City, of Brown Brothers & Co.; Archibald R. Graustein, New York City, president of the International Paper Co.; Frederick A. Geier, Cincinnati, Ohio, president of the Cincinnati Milling Machine Co.; Thomas E. Donnelley, Chicago, Ill., president, R. R. Donnelley & Sons Co.; Philip T. Dodge, New York City, chairman, International Paper Co.; William Butterworth, Moline, Ill., president

Deere & Co.; W. L. Clause, Pittsburgh, Pa., chairman of the Pittsburgh Plate Glass Co.; Ernest R. Behrend, Erie, Pa., president of the Hammermill Paper Co.; and Magnus W. Alexander, New York City, managing director, National Industrial Conference Board.

The visitors were the guests of A. M. Fine, vice-president of the Hudson Coal Co., and W. W. Inglis, president of the Glen Alden Coal Co.; who were assisted by H. M. Warren, electrical engineer, and S. D. Dimmick, vice-president and general manager, of the Glen Alden Co., and R. F. Buchanan, general manager of the Hudson company.

Both breakers were especially prepared for the reception of the magnates, placards explaining the use and capacity of each distinct piece of machinery. The tour of inspection started at the Marvine shaft and after the visitors had seen the freshly mined coal dumped on a conveyor line they followed the fuel through all stages of preparation. The conveyor, a 48-in. rubber belt, in two endless sections, each 550 ft. long, moved with its load at the rate of 300 ft. a minute to the top of the breaker. The belt carries 1,800 tons of coal a day. The visitors then followed the course of the coal from the top of the breaker through the chutes, jigs, shakers and separators into the coal pockets. The cleanliness of the surroundings elicited much comment.

## Gasoline Price Dependent On Coal, Says Teagle

Gasoline prices will be regulated by the market price for coal, according to Walter C. Teagle, president of the Standard Oil Co. of New Jersey, in a statement made public at Tulsa, Okla., recently. He based his prediction on an analysis of the petroleum situation by the company.

Under existing conditions gasoline can be obtained from fuel oil in many instances at a cost lower than it can be obtained from crude petroleum, Mr. Teagle said. "Fuel oil is sold in direct competition with coal," he said. "The reserves of coal are greater and more certain than reserves of petroleum and the price of coal so affects the price of fuel oil that gasoline is affected in proportion."

"Whenever gasoline can be obtained from fuel oil at a cost lower than the natural gasoline in the crude the tendency will be toward a reduction in the available quantity of fuel oil and an increase in the available amount of gasoline. A contraction in the supply of fuel oil will tend to enhance its value, whereas an increase in the quantity of gasoline will have the reverse tendency."

"When there is an overproduction of crude it is necessary for the industry to sell petroleum in the form of fuel oil in competition with coal and the consumers of gasoline will participate in the lower value so established."

## Blue Diamond Coal Co. Buys Old First Creek Mine

The first progress the Jewett, Bigelow & Brooks receivers have made in the disposal of any of the eight coal mining companies held in the group of that defunct concern was the sale on Nov. 6 of the old mine of the First Creek Mining Co. in the Hazard district to the Blue Diamond Coal Co., of Knoxville, Tenn., for \$100,000. The public sales in four localities the previous week at which the various properties were put on the block resulted in nothing. Few bids were offered and these were so low that the receivers got permission from Judge Cochran in the federal court at Covington, Ky., Nov. 6 to reject them all. An offer had been made of \$43,000 on the First Creek mine and \$27,500 for the Black Joe mine, in the same region.

The Hazard Jellicoe Coal Co. mine, the third of the J. B. B. mines of the Hazard field, is likely to revert to the Harvey Coal Co. This company is expected to lease it to some operating company soon in case no sale is completed. It is the largest J. B. B. mine in the Hazard field and it was announced that no bids for it under \$380,000 would be considered at the public sale. No bids for it were made at the time.

The public sales also failed to dispose of the J. B. Elkhorn Coal Co. and the J. B. Elkhorn Land Co., in the Elkhorn field; the Harlan Fox Coal Co., in the Harlan field, and the three Bell County properties, which are the J. B. Straight Creek Mining Co., the Roth Coal Co. and the Jaybee Jellicoe Coal Co.

## More Hot Shot for Union In West Kentucky

Some more hot shot have been fired into the remnant of organization of the United Mine Workers which is keeping a small part of western Kentucky tied up by strike. More public correspondence between District Attorney W. O. Smith, a former district president, and Wes Ames, the incumbent, has been released. Smith is trying to get Ames to sign an agreement with operators at a reduced scale in order to save the union from destruction. Ames asserts that Smith is disloyal to unionism but Smith invites attention to Ames' illogical position in part thus:

"Probably the miners of this coal field are not acquainted with the fact that you and practically every one of the principal officers of your district organization during the joint conference in Louisville in the month of April openly and strongly advocated a reduction in wages as being the only hope and salvation of your district organization.

"No doubt the miners of this coal field are not aware of the fact that you and your district secretary-treasurer and a number of other officers went to Indianapolis with the avowed purpose of asking the international officers to permit you to make a contract with the coal operators of this district carrying with it a 20 per cent reduction in wages.

"I am sure they do not know that

## Brotherhood Mines Now Running Non-Union

Although Warren S. Stone, head of the Coal River Collieries Co., which is the Brotherhood of Railroad Engineers' coal company, with four mines in West Virginia and Kentucky, told John L. Lewis, president of the United Mine Workers, that he did not want to run non-union, he is now doing so. The recent refusal of the miners' union to permit a cut in wages so that the railroad union could run its mines has driven Stone to action. He couldn't let his mines stay down forever. Mines Nos. 1 and 2, on Lick Creek, are still idle, but Mines Nos. 3 and 4, on Laurel Fork, are both operating non-union on the 1917 scale. The brotherhood company has evicted a number of union non-working miners and their families from company houses, which naturally wins much sweet and friendly comment from the miners' union.

after the St. Bernard Mining Co. had withdrawn from that conference and declared its intention no longer to deal with the United Mine Workers, you, Herman Vincent and ex-president Lonnie Jackson tentatively agreed among yourselves to ask Frank Rash, an officer of the St. Bernard Mining Co., to come back into the conference and agree again to treat with your organization upon the condition that you would agree to a 20 per cent reduction in wages, and that you were so indifferent and unconcerned at that critical period in your wage negotiations that after Mr. Rash had agreed to come back you let the golden opportunity to save and perpetuate your organization in the Hopkins County coal field slip by, refusing to carry out the suggested agreement with Mr. Rash."

Smith points out cases of suffering among western Kentucky miners and their families—wives pawning their wedding rings, miners selling \$75 milk cows for \$10, children barefoot in the frosty air, and men in the union begging—all because of bullheadedness on the part of union officials.

## New Haven R.R. Seeks Bids

J. F. Manning, fuel agent for the New York, New Haven & Hartford R.R., will receive bids until noon on Nov. 17 for delivering alongside the discharging plant at South Boston, Mass., between 360,000 and 410,000 net tons of high-volatile run-of-mine bituminous coal, in substantially equal monthly quantities between May 1, 1925, and May 1, 1926.

Coal traffic west bound through the canals at Sault Ste. Marie during October, according to the monthly report of the Corps of Engineers, U. S. Army, consisted of 1,643,308 net tons of bituminous and 57,850 net tons of anthracite. Of this, 8,733 tons of soft coal passed through the Canadian canal, the remainder going by way of the American canal.

## Grand Jury in Utah Indicts Promoters of Great Western Coal Co.

A mild sensation was caused at Salt Lake City, Utah, last week when it became known that the federal Grand Jury had indicted George A. Storrs, former warden of the State Prison and a leader in political and financial circles of the state, together with Joseph S. Welch, Earl J. Welch and Charles M. Croft on a charge of conspiring to defraud and with using the mails for that purpose in connection with their promotion of the Great Western Coal Mines Co.

The company recently became a mutual and was one of the best known of the many recent coal mining concerns to attempt to enter the field on the mutual plan. Among the witnesses called before the grand jury were members of the State Securities Commission, which had at different times authorized the company to sell stocks and bonds in the state. The Secretary of State and the Attorney General also were called. Each defendant has been released on a \$1,000 bond and the case is expected to come up for trial at an early date.

The indictments are based on charges that securities of the Great Western Coal Mines Co. were sold by misrepresenting the assets and intentions of the company. In support of the charges letters and documents were presented in an effort to show that money raised from prospective stockholders and bondholders was actually diverted, in whole or in part, to the payment of personal obligations of the individuals indicted. It is said the indictment terminated an investigation of nearly two years on the part of federal agents.

It is alleged that the men were taking money from the public for the development of assets which did not exist. It is stated in the charge that they never owned more than nine acres of coal land in the Gordon Creek region of Carbon County, where the property was situated, or in any other place.

Thomas Yates, secretary of the company, said the indictment will have no effect on the present organization of the company, and refers only to the pre-organization sales campaign. He sets forth a list of the property owned by concern and said they would be actually shipping coal this month.

The indictment appears to be against the officials and not an attack on the company as a business unit. H. C. Hicks, secretary to the securities commission, told a *Coal Age* correspondent. Mr. Hicks said the company was not originally classed as a mutual but its last application to sell stock, which was refused, would have placed it on a mutual basis.

Mr. Storrs, president of the company, is a former superintendent of the Spring Canyon Coal Co. and a former Sheriff of Carbon County. Storrs, the well known coal camp in Carbon County, was named in his honor. The Welches also are well known in Western coal mining circles.

## Coal Producers Jubilant at Outcome Of Presidential Election

Glad to Escape Democratic Regulation and Nationalization Theories of La Follette—Remedy for Overproduction Hoped For—Removal of Uncertainty on Trade Association Activities Expected

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Producers of coal are more than pleased by the outcome of the presidential election—they are jubilant. Ordinarily there are more Democrats among coal operators than among those in charge of many manufacturing industries, because none of them is influenced by the need of protective tariffs for his product. In this particular campaign, however, there were unusual reasons why coal operators gave their support to the Republican ticket, despite the fact that the Democratic standard bearer had served the industry in an important way in a legal capacity.

The resolutions committee at the Democratic National Convention allowed itself to be influenced by New England—a section which has much to say in convention but which furnishes the party no electoral votes—to insert in the platform a pledge “to regulate by governmental agencies the anthracite coal industry and all other corporations controlling the necessities of life.” While bituminous coal was not mentioned specifically, it was recognized that it is a necessity of life and was included in the platform declaration just as surely as if it had been mentioned specifically. As a matter of fact, all coal was included in the paragraph until Harry L. Gandy, secretary of the National Coal Association, persuaded Senator Walsh of Massachusetts that there could be no more justification for the mention of bituminous coal than any other commodity necessary to life.

### Demand for Individual Initiative

While that paragraph in the Democratic platform was enough to lose to the party all support from the coal industry, the principal reason for the general support given the Republican ticket was the vigorous stand of the party against the nationalization theories of Senator La Follette. As a matter of fact the best political analysts agree that the chief reason for the Republican landslide was the determination of the American people to stay “on the road of individual initiative, enterprise and opportunity along which American institutions so far have progressed,” to use Secretary Hoover’s phrasing.

As in Great Britain, the American public, in view of the Russian experiment, was glad to have an opportunity to demonstrate conclusively that it has no intention of turning into the road “which leads through nationalization of utilities to the ultimate absorption into government of all industry and of all labor.” Full advantage was taken of the opportunity to crush any tendency to put more government in business.

The election of the Republican ticket is regarded as the answer to the plea of the coal industry to be let alone, recently so effectively voiced by S. Pem-

berton Hutchinson, president of the National Coal Association, in his speech before the American Mining Congress. The danger of regulatory legislation has been swept away by the proved popularity of the Republican position on this major point.

### No Government Meddling

There is another important promise to the coal industry in the re-election of the Republican administration. It is preparing to take a definite step to free the oil industry of the great evil of overproduction. The interest which the coal industry has in that constructive effort has been pointed out previously in this correspondence. If it is in the public interest to stop overproduction in oil it would be in the public interest to encourage some plan which would prevent it in coal. While the details of the plan have not been announced, it is safe to say that the party will be consistent with the attitude it assumed during the campaign and not inject government meddling into business on the excuse of curtailing overproduction. In fact, it is known definitely that the plan as it refers to petroleum contemplates only sympathetic co-operation in a movement which will be directed by the industry itself.

Because of the way in which the people have spoken and because of the well established policies of the administration, the coal industry has little reason to anticipate regulatory legislation. There is going to be no attempt to shackle business with new restrictions. The administration’s policy is clearly revealed as being one looking to the fostering of business growth by allowing it the utmost freedom. For that reason it is logical to suppose that it will hasten to remove the uncertainty hanging over trade association activities. Of great importance to business in general is the fact that the two vacancies about to occur through the resignation of justices of the Supreme Court will be filled by a President who is certain to name to that all-important body men of proved conservatism and soundness.

Apparently the new administration is going to have enough backing in each house of Congress to carry through its legislative program. This augurs well for the coal industry and other industries, which will be benefited by a program of constructive legislation which will include tax reduction. Even in the matter of foreign relations definite progress may be expected. With the passing from the scene of the leaders in the League of Nations controversy bitterness is disappearing and a policy probably will be adopted which will be in the interest of world stability. The nomination of General Dawes as the Vice-Presidential candidate meant that

### Three-Cylinder Engine For Coal Service

The Louisville & Nashville R.R., Louisville, has just received a new three-cylinder type of locomotive, the first of its kind south of the Ohio and the fourth in the United States, made by the American Locomotive Co., which is testing out this new type of locomotive, which is said to have a considerably increased drawbar tractive power or pull, due to the third cylinder keeping heavy loads pulling steadily, without the intermission in power, as is the case with the two-cylinder locomotive, especially in hilly country. The new engine weighs 334,000 lb. exclusive of tender, and will be used between Corbin, Ky., and Louisville, in bringing up heavy coal and freight trains from southeastern Kentucky.

the Republican Party at that time had underwritten the Dawes plan. To the signature of the Republican Party now has been added the signature of the American people. Moral backing, as well as financial support, now is pledged to this particular project for the restoration of Europe. Instability abroad for five years has militated against the stability of business in this country. The Dawes plan promises prompt relief from that situation. As a result of all of this planning by business becomes possible as has not been the case for a decade.

### Farley Succeeds Birmingham As D. L. & W. Coal Head

Announcement on Nov. 6 that John F. Birmingham had resigned as president of the Delaware, Lackawanna & Western Coal Co. had been discounted considerably by rumors during the past several weeks that such action was contemplated. Recently Mr. Birmingham had resigned as a director of the Lackawanna Railroad Co. Mr. Birmingham’s successor as president is Elliot Farley, of Boston.

Mr. Birmingham became president of the coal company several years ago, having been promoted to that position from general auditor. He is one of the best known and best informed coal men in the industry. During the World War he took a prominent part in the distribution of coal and served on several federal state and city committees.

Mr. Birmingham resides at Oyster Bay, Long Island, where he takes a prominent part in civic affairs. He is a director of the Coal & Iron National Bank, New York City; trustee, Dime Savings Bank, Brooklyn; director, North Shore Bank of Oyster Bay, and a director of the State Bank of Sea Cliff, Long Island. He also is an honorary Deputy Police Commissioner of New York City. A brother, L. V. Birmingham, is secretary of the St. George Coal Co., of New York City.

Mr. Farley has taken charge at the New York office but declined to make a statement regarding his plans or policy.

## Practical Pointers For Electrical And Mechanical Men

### Why Waste Money to Place Electric Wires In Underground Conduits?

Overhead Wire Installation Around Mine Is More Economical—Appearance Afforded by Underground Wiring Not Important Consideration—Conduits Above Ground Eliminate Trouble

In the smaller cities where pole lines are used in the business section and where a large number of wires may enter a building, we can readily see why they are placed in underground conduits. Imagine the situation if all wires were carried overhead direct from the crossarm to the most convenient points of entrance through the outside walls! But around a mine, where sometimes no more than two or three wires enter a building from a nearby pole, why do we so often see the conduit brought down the pole, then underground and up through the floor to the switch cabinet or busbars?

This type of installation usually costs much more than the overhead; it is not so reliable and is always more difficult to repair. Generally the only advantage of an underground entrance is that it affords a neater appearance. However, it seems rather inconsistent to sacrifice other more important advantages for appearance alone, especially when we consider that the overhead entrance is still the approved method for city dwellings where neatness is a more important consideration than at the small substation, tippie, fan, or hoist-house of the average mine.

Fig. 1 is a sketch of an actual substation installation. The transformers

Fig. 2—Conduit from Pole Line

The expense of an underground wiring entrance to this hoisthouse, of cheap frame construction, appears out of place. Had the line been carried overhead it would have been much easier to install it.

are located outside the building in a fenced enclosure, and the 2,200-volt line is brought to a point above the buses through the rigid iron conduit A. A simple, cheap and more reliable method is shown by the dotted position B.

Fig. 1—Conduit Encases Wires from Transformers

The transformers supplying 2,300 volts to this substation are located outside and only a few feet from the building. There would have been no disadvantage in an overhead entrance.

Referring to Fig. 2, we see a sketch of another actual installation. Here an underground conduit is used to bring power into a cheap frame building which houses a small hoist. Fifty feet of 2½-in. conduit, indicated by A, is used. Method B would have required only 8 ft. of conduit and would have saved approximately 120 ft. of wire. Placing the conduit overhead would eliminate the risk of trouble from water which is always liable to enter an underground conduit through poor joints, by holes caused by corrosion or by terminal fittings which are not weatherproof.

### Coil Springs Used as Belts in Graphic Wattmeters

By making a few simple changes to the mechanism of their switchboard-mounted, graphic type, alternating-current wattmeters, R. F. Demi, chief electrician of the Keystone Coal & Coke Co., of Greensburg, Pa., is eliminating those aggravating troubles which formerly were the frequent causes of incomplete or imperfect demand-meter charts.

The meters are of the type in which a small motor, controlled by relay contacts, is used to move the inking pen. One such meter is installed in the main line at each operation. The continuous charts thus obtained are used to guide and stimulate the efforts of the organization toward holding down the 15-min. maximum demand which is an important factor affecting the power bills.

The common troubles encountered were the slipping of the flat leather belt driving the chart re-roll, to the climbing of sprockets by the chain connecting the motor to the pen mechanism, and the opening of circuits in the resistance units.

Both the chart re-roll and pen mechanisms were changed to belt drives using small coil springs as belts. This method, as compared to a leather belt, has the distinct advantage of maintaining a definite tension unaffected by use, time or climatic changes. New grooved pulleys for the re-roll were made in the local shop, but for the pen drive the old sprockets were altered to accommodate the coil-spring belt. This was done in a lathe by turning the teeth nearly off and then cutting a groove in the face. The belts were made by winding fine spring-steel wire on a mandrel about ⅜ in. in diameter.

The compact and rather inaccessible resistance units furnished with the meters were made up of short resist-

ance tubes of graduated size nested one inside the other. To eliminate the difficulties of repairing or replacing these resistance units they were replaced by a group of individual units each screwed into a socket so as to be easily removed for testing or renewal.

### May Easily Damage Meters by Wrong Connections

Portable direct-current millivoltmeters and ammeters are often damaged because many users do not realize the circumstances which cause a burn-out. The necessary practice at the mines of grounding one side of the direct-current line forms a condition which should in itself spell "Caution" to the electrician using shunt-type instruments on mine circuits.

Fig. 1 is schematic diagram of an ammeter and its shunt, connected for

Fig. 1—Lead Drops to Ground

Accidental connection of ammeter leads to ground frequently makes it necessary to send instruments back to the factory for repair.

testing the motor of a mine pump or other inside equipment. The natural tendency is to connect the shunt in the positive conductor as shown by the fine lines. With this arrangement, contact to ground by the shunt and of either instrument lead, will instantly burn the meter winding. This is liable to happen when the meter is being connected or disconnected, or it may be caused by a lead knocked loose from the shunt. The fine dotted line indicates how 275 volts may be thrown on

Fig. 2—Millivoltmeter Connection

Loosening of temporary connections made for resistance measurement has been the cause of damage to many low-reading voltmeters. Meter connections should be made independent of, and on the inside, of main connections A and B.

a 0.1-volt capacity instrument by the positive lead touching a rail.

The preferred method of connecting the meter into the negative circuit is shown by the heavy lines of Fig. 1. When this arrangement is used there is practically no chance of the meter being damaged by accidental connection of either of the shunt leads to the ground.

The use of a millivoltmeter or of any low-reading voltmeter for determining the voltage drop across a low-resistance conductor, which has been connected temporarily into a circuit, has many times resulted in damage to the meter. Fig. 2 shows the connection when determining the resistance of a series field coil. If the millivoltmeter leads are connected as in full lines no damage to the instrument will result should the connections A or B (generally rather temporary for such a test) come loose; however if connected as shown by the dotted lines the meter will be burned out. Under the latter condition practically full line voltage is applied to the low-capacity meter.

### Welding Galvanized Iron

The arc of an electrode is so stable that, with it, it is easy to weld galvanized iron. The most of the work to be done with this material consists in making butt welds or edge welds on thin plates, these welds constituting the seams in plates, pipes, etc. Welds are made with a single bead along the seam. The automatic welding machine, which affords great economies, is well fitted for work of this kind. Although hand welding is also employed to advantage, the methods used should be

Plate Thickness in In.	Electrode Diam. in In.	Current Approx. in Amp.	Speed in. per Minute
$\frac{1}{16}$	$\frac{1}{8}$	70-80	40
$\frac{1}{8}$	$\frac{1}{4}$	95-105	24
$\frac{3}{16}$	$\frac{3}{8}$	125-135	20
$\frac{1}{2}$	$\frac{1}{2}$	155-165	12
$\frac{3}{4}$	$\frac{3}{4}$	180-190	10

as nearly as practicable those about to be described below for automatic welding practice.

1. For seam welding, either butt or edge, the edges to be welded should be brought together closely and clamped and held in that position. For butt welding on thin metal, the edges should be clamped against a copper backing strip, to prevent burning through the

metal and to give a smooth seam on the underside of the work.

2. The electrode should be vertical to the work, or point slightly forward in the direction of travel.

3. Suitable sizes of electrode, values of current and speeds of travel along the seam are given in the accompanying table. The speeds are much higher than for ordinary welding. Those given in the table are conservative. Faster speeds may be used in many cases. The speed and the current used in all cases must be adapted to each other, more current being used with higher speed. With too little current for a given speed, slips will occur in the weld, whereas if the current is too great holes will be produced in the seam. The arc voltage recommended is from 14 to 16 volts, depending on the thickness of the work.

By a little practice with this kind of welding it is possible to train the operator to weld materials which now are being thrown away. Old parts may be built up and machined to size.

### Repairing Locomotive Axles

In spite of careful attention given to the lubricating of locomotive journals, the axles under hard service eventually wear. One of the many jobs that are facilitated by a large lathe, which makes the purchase of this machine a good investment, is the repairing of these worn axles.

Without taking off the wheels and driving gear, the worn journal bearing surface can be built up with an electric welder and then turned down in the manner shown in the accompanying illustration.

If worn axles are not repaired as described, they must be replaced. The latter job involves no little expense for, aside from the cost of the new axles, much time must be spent in changing and adjusting the spur-gear and wheels. Furthermore, the practice is not recommended because tight and true press fits of the wheels on the axles are not easily made.

Saving Money by Welding and Turning Worn Axles

It is a simple matter to build out a worn surface on the axle of a mine locomotive and later turn it down on a lathe. If the wheels are pressed off and on an axle whenever a repair must be made the wheels soon become loose.

# Production And the Market

## Halting Tendency Still Pervades Coal Business But Sentiment Is Better

A touch of cold weather in the Middle West last week was all that saved the coal trade from a further general decline, for in practically every other section of the country the demand fell far behind expectations. This was especially marked in Eastern markets and in Ohio, and to a less notable degree in Kentucky, where there is sufficient business in hand to keep the mines going for a while. The undertone is less firm in New England too, despite the fact that there has been a gradual pickup in the textile industry. As usual, the election is blamed in many quarters for the halt in business, though the result had been sized up fairly generally long ago. The consensus is that the outcome will benefit the trade, but insufficient time has elapsed as yet for the observance of any substantial effect. The impending close of navigation on the lakes is a conflicting element that is puzzling the trade, as it will throw such a large tonnage on other markets that the problem of absorbing it may be too difficult for solution. In that event some mines may be forced to close down until they are able to find an outlet for their product.

### General Business Impetus Promised

Business in general is expected to show renewed impetus from now on, according to most authorities, including the Federal Reserve Board, which reports increased production in most lines. Even those in which the gains have not been so marked show healthy conditions, the board states.

Coal Age Index of spot prices of bituminous coal receded another point last week, standing on Nov. 10 at 170, the corresponding price for which is \$2.06, compared with 171 and \$2.07 respectively on Nov. 3.

There was a further reaction in activity at Hampton Roads last week, dumpings of coal for all accounts during the seven-day period ended Nov. 6 totaling 325,568 net tons, compared with 363,818 tons the week before.

A slight increase in movement up the lakes took place,

dumpings at Lake Erie ports during the week ended Nov. 9, according to the Ore & Coal Exchange, being as follows: For cargo, 704,538 net tons; for fuel, 30,937 tons, compared with 688,548 and 38,272 tons respectively during the previous week.

Bituminous coal production receded during the week ended Nov. 1, when, according to the Geological Survey, 10,091,000 net tons was produced, compared with 10,300,000 tons during the preceding week, as shown by revised figures. The reduction was due to the partial observance of All Saints' Day as a holiday. In like manner, anthracite output fell away to 1,444,000 net tons, compared with 1,927,000 tons during the week ended Oct. 25. The comparatively larger loss in output

of hard coal was due to the general observance of Mitchell Day (Oct. 29) in addition to the church holiday.

Mild weather is proving a stumbling block to the anthracite trade, demand being slow and independent prices showing a tendency to weaken. With output curtailed, however, the movement has been strong enough to prevent accumulations. Dealers are well supplied with most sizes. Stove leads in demand and nut moves without much difficulty, but pea is in trouble. Rice and barley are the strongest of the steam sizes, buckwheat No. 1 being comparatively weak.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
Oct. 18.....	10,694,000	10,261,000

Cal. yr. to date (c)...	15,874,000	8,161,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

## Cool Weather Hits Midwest

The prayed-for cold wave rolled across the Midwest states late last week with a slight stimulation of domestic business, which had been pretty dull for the previous two weeks. However, the weather sharps were not sure the cold would remain long. Not all the domestic coal standing unbilled at mines was moved, but running picked up a trifle during the first two days of cold in anticipation of business. This, of course, slightly increased the output of screenings and did not, therefore, stiffen steam business.

The screenings situation in Illinois and Indiana is not particularly discouraging this week, however. The slowing down of mines lately due to inability to sell lump and egg has reduced the supply. On top of this a good many big buyers have been signing up steam contracts for the rest of the winter. Thus screenings in southern Illinois have been enabled to stand up closely to the circular of \$1.25@ \$1.50, central Illinois has quit selling dollar coal, Indiana Fifth Vein has stepped up to above \$1 and Indiana Fourth Vein is holding its own at \$1.40@ \$1.50.

The election had almost no immediate effect on the coal trade although the wise observers expect a steady but slow improvement in industrial business from now forward. The Midwest region is more directly affected by weather and freight rates than by voting. The new weather is encouraging but the reduction in rates on eastern Kentucky and

other inner crescent coal to the Northwest is distinctly discouraging to Illinois and Indiana. Southern Illinois only recently was hurt by the 28c. rate increase to the Twin Cities, thus giving dock coal an edge over most Midwest output; and now comes the I. C. C. order reducing L. & N. coal 15c. to the Northwest.

Coal business has slumped off at St. Louis. Warm weather had stocked up the yards and there is, very little demand except for a little high grade. There is a further increase in the number of homes that are not buying coal this year, and a survey by some dealers shows that oil-burner competition is growing. This also is affecting the mines, and yet the mines and the dealers are not spending any money to retain the business that they had. Wagonload steam has eased off. Carload steam is slow locally and there is no demand from the country. Country domestic has also fallen off.

## Little Change in Kentucky

Kentucky prices continue fairly steady over the week, no material change being reported in anything. Demand has not been as active as had been expected, but there is enough business in hand to keep mines going for a while.

Southern coal is moving north freely. During October all previous records were smashed on the Louisville & Eastern division of the Louisville & Nashville R.R. out of the

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924		1923	
	Nov. 10	Nov. 3	Oct. 27	Nov. 12
Index .....	170	171	176	184
Weighted average price.....	\$2.06	\$2.07	\$2.12	\$2.23

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

Hazard and Elkhorn districts, while the total coal car loadings for the entire system were smashed during October, the road having handled heavy tonnage from all fields.

Prices are \$3@3.25 for best block in both eastern and western Kentucky, with some eastern quoted at as high as \$3.50, but without much new business booked at over \$3.25. Screenings in western Kentucky are a shade firmer at 65@75c. a ton, while eastern starts at 85c. and goes to \$1, with just a little tonnage quoted at \$1.05@1.10.

Mine run has been moving very slowly in view of the fact that screenings are in good supply, and at low prices. Even nut sizes are low as a result of considerable screening of nut, western Kentucky quoting small nut as low as \$1.60, with big nut at \$2.10, and eastern Kentucky, producing nut in only a very few mines, is quoting \$1.75@2. Western Kentucky is asking \$2.50@2.75 on egg and \$2.75@3 on lump, while eastern is asking \$2.25@2.50 on egg, and \$2.25@2.75 on lump.

### Northwest Feels Better

A feeling of distinct optimism pervades the coal trade circles at the Head-of-the-Lakes as a result of the presidential election. Dealers are looking forward to an improving demand for steam and gas coal to set in almost immediately from industrial quarters. Colder weather during the last ten days also is contributing to good inquiry from retailers over the Northwest, who are at present carrying limited supplies. A feature on the market was the speeding up of inquiry for Pocahontas prepared. That led to another advance of 50c. to \$8.50 as compared with \$7 early last month.

Receipts at Duluth and Superior docks during October

aggregated 1,196,833 tons, including 1,151,086 of bituminous and 45,748 of anthracite. That brought receipts of bituminous as of Nov. 1 to 6,362,663 tons and of anthracite 1,177,271 tons. Top figures for the year were set in shipments from the docks over the Northwest during October, the aggregate being reported at 26,418 cars as compared with 24,373 cars during September and 23,436 cars during October last year.

Coal is coming to the Milwaukee docks quite freely, but demand is faint. After a slight flurry due to an ominous drop in temperature the flow of orders waned with the recovery of the mercury. Dealers say everything depends upon the weather, which has been unseasonably warm. October receipts of coal by lake—cargo and car ferry—were larger than the receipts of any other month in 1924. Cargo totaled 120,640 tons of anthracite and 423,064 tons of bituminous coal, or 543,704 tons in all. Cargo totals for the season to Nov. 5 are 693,294 tons of anthracite and 2,130,474 tons of bituminous coal, or 2,823,768 tons in all, as against 813,824 tons of anthracite and 2,741,963 tons of bituminous coal—3,555,787 tons in all—during the same period in 1923.

At the Twin Cities September and October consumption was only one-fourth of the usual moderate volume that is burned in those months. The deliveries from the docks this fall to this region as compared with last show a loss of 25 per cent. Despite this depressed circumstance, the market position of practically all grades of coals, except screenings, is firm. Dock prices are holding to their list as they have been doing. All-rail coal is firm at the ruling prices, and there seems to be little surplus coal seeking an outlet. Dock prices remain the same as they have been for some time.

### West Needs Cold Too

Continued warm weather has brought the domestic market in the Southwest almost to the vanishing point. A considerable surplus of prepared grades has accumulated at Kansas and Oklahoma mines, although these operations are now averaging only about half time. The curtailment of production has resulted in cleaning up the surplus of screenings. Industrial demand is constant.

Continued warmth throughout the Colorado territory has shown its effect upon the coal business. This is the first time in twenty-two years that Colorado has experienced an October without a snow. Production last week showed a slight pick-up, however, and Colorado mines worked an average of 32 hours. The "no market" hazard is slowly being overcome, as only 20 per cent of the total working time lost was due to this cause. Prices are unchanged.

In Utah the unseasonable weather is reducing production. Working time is not over 50 per cent. Prices remain firm, both wholesale and retail, except that retailers are beginning to cut the price of slack. Industries other than the metals are buying very little coal.

### Ohio Business Sags Some More

Gorged markets to the north in conjunction with balmy weather has caused a further break in prices at Cincinnati, only slack holding its own, urgent buying by lake interests for the last run of the boats north before the close of navigation causing it to advance slightly. Even mine run, which has been only casually affected by the recent upward trend, was forced to back water a little. The domestic sizes have been badly shot. J. A. Morris' figures show that 13,345 cars loaded with coal passed through the gateways last week, only a few cars less than record figures.

Domestic demand at Columbus has turned dull as a result of warm weather. Buying is limited strictly to immediate wants. Retail prices have been rather firm up to a few days ago, when some cutting was reported. Steam trade is rather quiet, as reserves are still sufficient and purchasers are loath to increase them. Demurrage coal is selling on the open market at low prices. Industrial conditions are still unsettled. Lake trade is about over for the season, which is expected to throw a large tonnage of West Virginia screenings on the market which is now going to the lakes. The output in Ohio fields has shown a decline.

Business in the Cleveland market is slower for this time of the year than in many years. Demand is low and run-of-mine prices have softened 10 to 15c. per ton; some odd lots of distress coal from other districts than No. 8 Ohio have sold for even less. Mild weather continues to hold down the domestic trade and steam consumption seems to

be at a minimum, buyers apparently not caring to lay in any sizable quantities.

### Prices at Pittsburgh Withstand Pressure

Demand at Pittsburgh continues dull. There has been no shipping of coal on consignment to any appreciable extent, and thus there has been no "distress" coal, but there is a possibility that consigning of coal will be resorted to. There is no accumulation of loaded coal at mines threatened at present with demurrage. Prices are unchanged.

Demand continues light at Buffalo, as compared with the supply, which means a trade without much in it for the seller or anybody else but the consumer. Some sanguine people believe that the low point has been passed, but it is too soon to say what the election will do. Price quotations have not changed to amount to anything for months; they are still weak. Competition from West Virginia and Kentucky coals continues. The lake trade is dull and apparently about closed for the season. Shipments to November are 2,380,150 tons compared with 2,485,020 tons to the same time last season.

### New England Market Less Firm

In New England there is less indication of firmness than a week ago. The sales agencies seem again to have overreached slightly as to price, and coal has been purchased at from 5@10c. less during the current week. The trade is being made to realize there is as yet nothing in the industrial situation to warrant predictions of more than gradual improvement during the winter months.

At Hampton Roads small accumulations are again heard from. However, output is on a better scale, and it is simply that there are fewer buying orders in the market. Purchases are more spasmodic, and those who felt a fortnight ago like running to cover are now inclined to test the trend of prices and buy only on favorable openings. As usual in such situations there have been cancellations to upset the calculations of producers, and where late in October the latter felt like putting brakes on sales they are inclined now to make small concessions in the interest of a higher average output. Spot cargoes range \$4.25@\$.4.40 per gross ton, f.o.b. vessel for Navy acceptable grades. For prepared coal moving west there appears to be a stable demand.

On cars Boston for inland delivery the volume of coal handled has somewhat decreased lately, although prices are reasonably strong at \$5.40@\$.5.50 per gross ton. At Providence and at Portland competition is less acute and factors are able to obtain a more remunerative gross price.

On coals from central Pennsylvania all-rail there is practically nothing more than the staple business for special uses that materializes every year regardless of competition from Southern coals at tidewater. Prices show no material change.

### Atlantic Seaboard Markets Inactive

There is scarcely any activity in the New York market. Buyers show no anxiety when warned of a possible car shortage or transportation difficulties. Shipments to tidewater passed the 2,000-car mark one day last week, but tonnage did not accumulate. While most of the arrivals were either on contract or on order there was sufficient free coal to meet all demands and to keep the market unsettled.

The boom that was expected after election is slow to materialize at Philadelphia. Mild weather continues to be

a deterrent, but buying by the railroads is improving. Regular commercial contracts also are productive of good business, for prices are better than for spot business. Spot prices hang at the same low level. Most mines are still on a 50 per cent basis, with plenty of them doing less work.

At Baltimore no life is shown in any branch of the steam or gas coal trade, but improvement is hoped for with the passing of election. The spurt of a few weeks ago was short lived and prices have gone back to the late summer level. The first week of November saw no export clearances of coal.

The Birmingham steam market is on the upgrade. The movement of spot coal is showing some increase week by week as additional business is taken on by the mines and contract customers are taking more liberal consignments. This is especially true of the railroads, which have increased their weekly quotas around 10 per cent over what they have been taking for weeks past. The seasonal demand from oil mills, compresses, gins and saw mills is providing an outlet for a good tonnage in the aggregate, and the hydro-electric companies are using a great deal of coal at their steam plants and will continue to do so until the drought is broken.

### Anthracite Demand Disappoints

Slow demand and lower prices for independent coals prevailed in the New York anthracite market during the last week, as weather conditions were not conducive to heavy coal burning. Movement, however, was heavy enough to prevent an accumulation of coal. Retailers have full bins of most sizes and add to their supplies only when assured of receiving a pro rata share of stove, which continues to lead the demand. Egg is giving the most trouble of the larger sizes. Chestnut moves fairly easily. The poorer grades of pea coal can hardly be moved even though quoted about 50c. less than the better coals. Demand for this size is extremely slow. Buckwheat No. 1 is the weakest of the steam coals; rice and barley are in better demand.

Because of the October shortage due to the flood, shippers have plenty of orders, but retail trade at Philadelphia is only moderate. The retail price situation is stronger since the independents have increased mines prices for November. The most wanted size among dealers continues to be stove, although more nut is being sold at retail. Steam coals are in better demand. Independents are moving nearly all of their production without price cuts.

Anthracite dealers at Baltimore have been looking askance at the growth of oil-burning equipment, due to the cost of domestic sizes of anthracite. The new equipment recently put on the market to consume buckwheat coal in the ordinary home is being watched with interest.

Trade has improved a little at Buffalo. There has been so much unseasonably warm weather that the consumer has had nothing to do but burn a little gas. All he wanted was stove and chestnut and of course if he was able to buy only furnace sizes he was distressed and refused to buy at all. The coke trade is still quiet.

## Foreign Market And Export News

### Slight Upturn in British Coal Market; Output Above 5,000,000 Tons

Though the South Wales market is still in an unsatisfactory state, a gradual improvement is discernible. Interest has been revived in steam coals by the announcement that some important contracts for supplies over the next twelve months have been booked. Fewer price concessions are being made. Coal stocks are large, except the best smalls, which are scarce.

The Newcastle market is somewhat steadier though business is still very poor. Inquiry for current shipment has improved and some of the collieries are negotiating for November output. There are no contracts to report though two European gas works have taken 3,000 tons of gas coals for delivery next month.

Production by British collieries during the week ended Oct. 25, a cable to *Coal Age* states, was 5,061,000 tons, according to the official reports. This compares with 5,147,000 tons produced during the week ended Oct. 18.

#### French House Coals Active; Industrial Inquiry Dull

The general position of the French coal market is unchanged. Inquiry for industrial fuels is dull, but for house coals there is more activity, due to seasonal requirements. Stocks are not large and prices are firmly maintained.

The Nord and Pas-de-Calais are now trying to make up for the delays in shipments during September.

Imports of British coals, which fell off during the week ended Oct. 17 to 125,000 tons, increased the following week to 181,500 tons from South Wales alone. Prices are steadily falling at the shipping docks, and in spite of sterling being maintained at 86f. the margin between British and French prices (delivered) has lessened to the point of being rather dangerous in certain regions where British and French fuels enter into competition.

The shortage of rolling stock in France is less pronounced.

The M.I.C.U.M. ceased to function in the Rhenish-Westphalian Basin on Oct. 28. An organization to regulate the importation of German coals hereafter is under consideration. It probably will be controlled by the state and administered by representatives of French collieries, importers, merchants and leading consumers. At a recent meeting held at the Ministry of Public Works no agreement could be reached owing to divergence of views regarding the transport of coal by the Rhine.

During the first eighteen days of October, France and Luxemburg received 287,700 tons of coal; 213,700 tons of coke, and 21,600 tons of lignite briquets, a total of 522,600 tons. The daily average of 29,000 tons compares with 31,600 in September.

Between Oct. 23 and 29 the O.R.C.A. was supplied with 24,250 tons of coke through Ehrang and 31,215 tons through Aix-la-Chapelle, a total of 55,465 tons or scarcely 8,000 tons a day.

#### Hampton Roads Outlook Bright; Prices Hold Their Own

Business at Hampton Roads showed very little change, with prices holding their own and with prospects for better movement growing brighter. Coastwise business has been fair, bunkering good, and foreign shipments tend downward.

Prices reflect somewhat increased shipments to tidewater, and a number of inquiries from New England have had the effect of putting a more hopeful tone in the market. Domestic business is somewhat better in the retail trade, and optimism is the keynote of the situation.

Shippers have much faith in the effect of the presidential election on general coal movement, whether the effect is actual or imaginary.

## News Items From Field and Trade

### ALABAMA

Final details of the Sloss Sheffield Steel & Iron Co., Alabama Co. merger are being worked out in New York by officials of the two corporations and the agreement probably will be made effective Nov. 15.

Fire, said to have originated in the offices of the Piedmont Coal Co., at Dora, Walker County, Nov. 5, spread to adjoining buildings and caused damage estimated at \$40,000. Shortage of water necessitated the dynamiting of a building to stop the progress of the flames.

W. L. Smith and associates, operating the Raccoon Coal Co., at Altoona, in Etowah county, are now producing coal from their No. 4 mine at the rate of 150 tons per day, with the expectation of increasing the output to 500 tons per day soon.

A \$6,000,000 merger was effected Nov. 1 with the completion of negotiations by the Alabama Byproducts Corporation, controlled by Morris W. Bush and Horace Hammond, for the acquisition of the Pratt Consolidated Coal Co. and its subsidiary, the Globe Coal Co., of Birmingham, owned by George B. McCormack and Erskine Ramsay. The consolidated company will control 110,000 acres of land in Jefferson County with more than twenty mines having an annual output of 2,500,000 tons of coal. The Pratt Consolidated company had been on the market for some years, Messrs. McCormack and Ramsay having offered it to the Tennessee Coal, Iron & R.R. Co. and having on several occasions been in negotiation with the Walter Moore interests.

Fire of unknown origin starting in the commissary building of the American Fuel Co., Beltona camp, on the morning of Nov. 2, destroyed the building and contents and also supply houses, office and garages located nearby, entailing a loss estimated at \$50,000. Beltona is located in the northern section of Jefferson County. Employees of the company were unable to make any headway in fighting the flames on account of the scarcity of water due to the long drought. It is stated that construction of new buildings to replace the burned structures will begin at once.

### ILLINOIS

The mine at Niantic, which has been closed since last April, is now hoisting coal regularly. Sixty men are employed, which number will be increased soon to 100. The coal is trucked to Decatur, ten miles east, where it will compete with the Decatur mined coal.

The Franklin County Coal Co. has made extensive improvements at its mine at Sandoval and expects to have it in operation soon.

The Wolf strip mine, near Belleville, just off the Freeburg-New Athens road is now in operation. A switch has been laid to the mine from the Illinois Central at Lementon.

A. A. Bryden, formerly Southwestern Sales Manager of the Southern Gem Coal Corp., at St. Louis, is appointed Southwestern Sales Agent for the Saline County Coal Co. of Chicago. He has offices in the Wainwright Bldg., in St. Louis.

George Adams, of Matherville, has been named manager of the Rex mine, near Warner. Mr. Adams takes the place of Thomas Mills of Rock Island, who was accidentally killed at the mine recently.

An investigation of the fire which destroyed the uncompleted shaft and works of the Devalley Coal Co., on the Urbana road six miles west of Danville, disclosed the fact that the fire not only was incendiary but that the bottom works were dynamited before the fire started.

The Lovington Coal Co. mine near Lovington, which was reopened by local capital late in September after having been shut down all summer, is closed again for lack of business.

A claim of \$200,000 against the defunct Southern Gem Coal Corporation has been allowed the Willis Coal & Mining Co., of St. Louis, Mo., by Judge English in the federal court of East St. Louis. Also the court permitted the Willis company to cancel a lease and take back full control of two mines in Perry County which the Southern Gem had never operated to any extent and which are now flooded.

James Steel has resigned as superintendent of the St. Paul Coal Co.'s mine at Ladd, and has removed to northern Wisconsin to reside. He has had charge of mines in the Ladd and Cherry regions for a number of years.

### INDIANA

Three men were killed early this month in an explosion in the Blackhawk mine of the Miami Coal Co. twelve miles east of Terre Haute. The three were substitute shot firers on their first trip down, replacing men who had been injured in a blast in the mine only a few days previous. A windy shot is

thought to have caused the latest explosion.

New developments in the Sullivan County coal field are expected by a merger recently consummated. W. H. Leland, of Chicago, until recently, president of the W. H. Leland Coal Co., with mines in Kentucky, Indiana and Illinois, has joined forces with the J. Wooley Coal Co., one of the oldest individual companies in Indiana and a pioneer company in the Sullivan County fields. The company intends developing holdings in Sullivan County. A diamond drill is on the Wooley property testing underground conditions in that vicinity. J. D. McInnes, who for thirteen years has been with the Wooley company, has been retained as superintendent.

### KENTUCKY

At Madisonville, the property of the Pontiac Coal Co. was sold at public auction on Nov. 4 to the Pontiac Coal Mining Co., for \$19,320. The property was sold to satisfy company creditors.

The Black Joe Coal Co., at Butterfly, Perry County, in the Hazard field, owned by the J. B. Stores Co., interests, Cincinnati, has been sold by the receivers to W. E. Davis, of the Midland Mining Co., at a reported price of \$26,000.

Recently the Franklin Circuit Court, at Frankfort, held a 1 per cent oil production tax unconstitutional. The case is pending in the Appellate Court, and a number of suits for recovery of taxes paid also are pending in state courts. Every Legislature in years has had a coal tax bill before it, but none has ever passed such a tax bill.

L. F. Brashears, of Hazard, was the highest bidder on the plant of the Harveyton Coal Co., at Harveyton, one of the properties of the J. B. Stores in the First Creek field, which went into hands of receivers about a year ago due to unsatisfactory business conditions. Mr. Brashears' bid was \$43,000. It includes the lease, mines, machinery, property and the commissary of the J. B. Stores. The mines have been operated by the receivers, J. B. Rickey and others, since last winter.

The Kentucky Washed Coal Co., at Nonell, which was out of the game for some months as a result of a landslide which wrecked its fine washer and tipple, is now producing heavily, its strip production on Oct. 29 totaling 31 cars of coal. A new washing plant, equipped with drying and dewatering systems,

is being installed by Krehbiel & Co., engineers, of Chicago, and will be in operation in December, replacing a temporary washer which has been in use since the plant resumed a few weeks ago.

### MINNESOTA

An interesting talk on coal conditions in the Northwest was broadcast over the Twin City radio central, WCCO, last week by F. O. Brandt, of the Northern Coal & Dock Co., St. Paul. He touched upon the tendency to hold back in buying and the result of piling up orders when the rush comes, along with a possible turn of cold weather.

There has been a final attempt to meet the low prices on coal from western Kentucky over the L. & N. and the M. & St. L. to the twin cities district. Other roads evidently became tired of having an adverse competitive rate and started tariff rates to meet them for the entire Northwest. This started opposition from the coal trade, which did not want to have the rate fabric upset completely. The dock association and the Franklin County operators were agreed in opposition to this step and have initiated efforts to have the matter adjusted without a complete overturning of present rates.

### NEW YORK

The Bethlehem Steel Co. has completed a new battery of 57 coke ovens at its Buffalo plant and will put in a second unit of the same size at once, replacing the old and somewhat out-of-date equipment formerly used. The company has its own mines and will use 1,000 tons of coal a day for coke making. The old process of 18 to 20 days now gives way to one that requires only 12 hours.

### NORTH DAKOTA

The fire which has been burning for more than a year in the lignite mine of the Haynes Coal Co. has assumed serious proportions again. It was once thought to be in control but a breakdown of pumps permitted its further spread. There is some danger of the

fire getting across the state line—or under it—and into the coal seams of South Dakota.

### OHIO

A small mine of the Dean Coal & Coke Co., located at Moxahala, was sold at receivers sale Nov. 3 to Charles A. Bruner, of Columbus, at his bid of \$4,100. The property had been appraised at \$20,516.60. The new owner will operate the property to supply his retail business in Columbus.

Several coal mines in the Bailey Run field which has been almost completely idle for months, started recently, operators announce. More than 300 men were given employment.

Eight members of the mining division will meet during the week of Nov. 17 at Pomeroy to obtain specific instructions for the most extensive first-aid and mine rescue campaign thus far conducted in the state, Chief Watson announced. The following week the remaining nine members of the division will meet at Cambridge to learn of such plans for their respective districts.

Fire, said to have been of incendiary origin, on Nov. 1 completely destroyed the tippie, power plant and other surface buildings at the Middle States Coal Co.'s Mine No. 24, near Jacksonville. A presumed attempt also was made at the same time to destroy the tippie of the company's Mine No. 68, about a half-mile south of No. 24, by use of explosives. Little damage was done at Mine No. 68, but the loss at Mine No. 24 is estimated at \$60,000, the tippie having been old but in good repair. Trouble is said to have arisen over the use of mechanical loaders and the operation of the mines on a co-operative basis, with the result that about one hundred men formerly employed at the mines were thrown out of employment. The leasors of the mines assert that the union scale was being paid for all hired day men.

Jerome Watson, Chief Deputy of the Ohio Department of Mining, has discovered that fire is still burning in the Doanville Mine which started Dec. 19, 1920. The openings were sealed up at that time and it was believed that the

fire had been extinguished but upon opening it recently it was still smouldering. Efforts will be made to fight the fire in order to get the mine in condition for operation.

### PENNSYLVANIA

Failure of the Legislature to make a specific appropriation for conducting examinations for the office of state mine inspector has placed Joseph J. Walsh, head of the Bureau of Mines, and his department in a rather embarrassing situation. It is understood that the state Department of Mines and Mining is without sufficient funds with which to conduct the examinations, defray the expenses of a hall, etc. As a result, Chief Walsh has had to turn to the state Department of Education for aid.

Dr. W. S. Blaisdell, a well-known coal operator of central Pennsylvania, was elected to the state Senate from the Indiana-Jefferson County district in the Republican landslide last week. The term is four years, during which there are two sessions of the Legislature.

Erection of a breaker has been started near Shamokin by Madiera, Hill & Co., owners of collieries at Natalie and Greenough. The new breaker, which is to be of steel construction and equipped with the most modern machinery, is intended to prepare the product of both the Natalie and Greenough mines, taking the place of the antiquated breakers now in operation at these collieries. These will be destroyed as soon as the new breaker starts in operation. The company has already erected an office building and a mule barn near the site of the new breaker.

The Susquehanna Collieries Co., has begun an improvement campaign in the collieries in the Mount Carmel section. The Richards Shaft, which is particularly gaseous, has a new fan with a capacity of 150,000 cu.ft. per minute. It is run by electricity furnished by the mammoth power house of the company. An even larger fan will soon begin its work of clearing the mines of gas and circulating air through the workings at the Scott colliery and the Pennsylvania colliery also will be equipped with a similar fan.

The Warner Youghiogeny Coal Co. of Pittsburgh, has contracted with the Roberts & Schaefer Co. for the installation of Marcus screens and R. & S. loading booms in its tippie at Charleroi.

Four men were seriously burned in an explosion Nov. 5 in the mine of the Hustead-Seamons Coal Co., at East Millsboro, 1½ miles from Brownsville. The men were drilling with an electric drill, it is believed, when a spark from the machine ignited a gas pocket. A sheet of flame enveloped the room. The miners were hurled to the floor of the coal seam, their clothing on fire. The explosion did not extend beyond the one room, and did not damage the workings.

The old Neilson mine in the western portion of Shamokin, which was aban-

Portion of Louise Town Site

This modern mining camp is at the Louise operation of the Bertha-Consumers Co., located at Louise, Brooke County, W. Va. The mine has a daily capacity of 1,500 tons.

done in 1902 during the miners' strike, has been taken over by a group of outside capitalists and operations will be resumed in the near future. New rock slopes are planned and modern hoisting machinery also will be installed. The company which has taken over the mine also has obtained valuable concessions from the Susquehanna Collieries Co. and the Lehigh Valley Coal Co. It is expected the new working will give employment to between 1,000 and 1,200 men and boys.

A tribute to the popularity of W. J. Richards, president of the Philadelphia & Reading Coal & Iron Corporation was paid in the Pottsville field on election day. Mr. Richards was one of the Republican electors in Pennsylvania and he received hundreds of votes above the totals cast for the 37 others on the ticket. In Fost township, Schuylkill County, more than 100 Democrats, all coal miners, split their tickets so that they could vote for the coal operator.

Announcement has been made by the Philadelphia Coal & Iron Co. of the promotion of Richard F. May, assistant to the division engineer in the Shamokin district to the post of division engineer in the Mt. Carmel field. Mr. May succeeds Albert R. Harris, who has been advanced to the position of general superintendent of the Locust Gap colliery.

## UTAH

J. A. Stallings, sales manager of the Spring Canyon Coal Co., Salt Lake City, is described as a "very sick man." Mr. Stallings has been ill for some months, but recently returned to his desk for a short time in an unsuccessful effort to attend to his duties. He is now in the hospital.

Approximately 160 acres of coal land in Grand County is to be offered for lease by the register of the Salt Lake Land Office, Nov. 17. The lease is made on application of John G. Adams. The terms are a royalty of 10c. per ton of coal mined, for production in the fourth year after the lease of 1,600 tons and for expenditure of not less than \$3,000. The lease will be awarded the person or persons bidding the highest premium above these terms.

## WASHINGTON

Enrollment is fairly heavy in the night schools conducted by the Pacific Coast Coal Co. for its employees in the mining towns of Carbonado, Black Diamond, Burnett, Newcastle and Issaquah. These classes, open to any employee, have been running for two years, offering grade school work and especial aid for foreigners who wish to become American citizens. This work is directly in charge of H. J. Hoff, a graduate of Bethany College, Lindsborg, Kan., who has studied in Germany, Russia, Italy and France and who received the degree of doctor of philosophy at the University of Illinois in 1908. He is assisted by R. R. Sterling, a graduate mining engineer, and by Mrs. C. C. Christenson, a graduate of Oberlin College.

## WEST VIRGINIA

All records for the shipment of coal from Norfolk & Western Ry. territory during the last two years were broken in October, it has been announced by the company. The company handled 62,731 cars, or more than 3,000,000 tons of coal, between Oct. 1 and 28.

W. A. Phillips, president of the Pemberton Coal & Coke Co., in the Winding Gulf District; of the Ashland Coal & Coke Co., in the Pocahontas district, and Majestic Colliery Co., located in the Williamson field, is still a patient at the Lankenau Hospital, in Philadelphia. The home of Mr. Phillips is at Mt. Carmel, Pa.

The following changes have been made in the operating organization of the Elkhorn Piney Coal Mining Co.: Lew Roach, formerly general superintendent of the Powellton (W. Va.) division, has been promoted to general manager of all mines, vice D. R. Phillips, resigned. Mr. Roach will continue his office at Powellton. J. W. Ailstock, formerly mine superintendent at the Weeksbury (Ky.) division, has been promoted to general superintendent of the operation of Stanaford, W. Va., vice F. M. Addis, resigned.

## WISCONSIN

The C. Reiss Coal Co. docks and two ore docks belonging to the Chicago Northwestern R.R. at Escanaba were damaged by fire Oct. 31. A fireman lost his life and property estimated to be worth \$2,000,000 was wiped out. A huge stock of anthracite on the Reiss dock was partly reduced by the flames. Several days' work was necessary to save the unburned part of the stock.

## WYOMING

The Union Pacific Coal Co. is co-operating with the city of Rock Springs in preparing plans for a city sewerage system and in the diversion of Bitter Creek from the center of the city to the northern and eastern side of Rock Springs. The project will cost several hundred thousand dollars.

The Lion Coal Co., operating at Lionkol, in the Rock Springs district, on Oct. 31, closed its properties at that place for an indefinite period, giving no reason for the shutdown. The properties have a production of from 1,200 to 1,400 tons daily, employing 155 men. The Union Pacific Coal Co. properties also were working slack the latter part of October, light freight shipments lessening the demand for their output.

The Union Pacific has discontinued fuse shotfiring in the Rock Springs district and has returned to electrical firing by a shotfirer after the day shift goes off.

## CANADA

Howard Stutchbury, coal commissioner for Alberta, in reply to an inquiry from the Federal Coal Committee at Ottawa as to whether the Alberta mines could supply coal to central Canada this winter, stated that al-

though production would be much below normal there is no reason why a considerable tonnage should not be available for Ontario provided freight rates are adjusted, the present rate of \$12.70 per ton being prohibitive. Production in Alberta will be speeded up if due notice of Ontario requirements is received.

The total output of the Dominion Coal Co. for September was 273,374 tons an increase of about 40,000 tons over the August output but less than the production of September, 1923. The success of the longwall system of mining at Sydney Mines has encouraged the management to put it into operation in other collieries.

The operators of all the mines in the Edmonton coal field, with the exception of the Penn mine, have expressed their intention of signing a contract with the miners on the terms of the award of the conciliation board. There will, therefore, be no walk-out, not even at the Penn mine, according to officials of the Edmonton District Federation of Miners.

Premier Greenfield, of Alberta, has announced that the following will compose the commission to investigate the coal-mining industry of the province, in accordance with a resolution passed at the last session of the Provincial Legislature; S. M. Evans, of Edmonton, chairman; R. G. Drinnan, director of the Mountain Park Collieries and of the Luscar Collieries, and Frank Wheatley, president of the Alberta Federation of Labor. The commission will start work at once and will thoroughly probe all phases of the coal-mining industry in Alberta.

## New Companies

The Richard Coal Co. has been organized at Huntington, W. Va., with a capital stock of \$100,000. Chiefly interested in the new company are, R. H. Williams, T. J. Fisher, J. F. Eaton, J. W. Fitchett and M. L. Burnett, all of Huntington.

The Gould Road Coal Co., 102 N. 3rd St., Steubenville, Ohio, has been chartered with a capital of \$30,000 to mine and deal in coal at wholesale and retail. Incorporators are: Andrew Pipo, Harley S. Thompson, Clyde Robeson, William Jacobs, John Hostovitch and Marshall N. Duval.

The Harmon-Burton Coal Co., Zanesville, Ohio, has been incorporated with a capital of 1,000 shares, no par value designated, to mine and deal in coal and coke. Incorporators are: William S. Harmon, H. P. Dean, Robert E. Marshall and Emmet R. Curtin, Jr.

The Lyell Coal Co., of Huntington, has obtained a charter providing for the issuance of 400 shares of stock of no par value. The incorporators are connected with the W. E. Deegans coal and mining interests of Huntington, where the new company will have offices in the Deegans Building. The company will operate mines on Keeney's Creek. Incorporators are: J. F. Grimet, I. F. Vass, A. W. Fitzwater, H. N. Priddy and F. H. Hall.

The Lincoln Coal Co., Covington, Ky., capital \$250,000, has been chartered by Irvin Davis, August Helm and H. H. McLean.

The Black Diamond Coal Co. of Gravity, Iowa, has been incorporated with a capital of \$50,000, to mine and sell coal. The company has the following officers: E. D. Morris, president; George W. Evans, vice-president, and H. E. Davidson, secretary-treasurer. The company has sunk a mine, finding a 26- to 28-in. vein of coal at a depth of 200 ft.

## Traffic

### New Coal Rates Approved by New York Commission

The New York State Public Service Commission has approved the new tariff schedule of the Buffalo, Rochester & Pittsburgh R.R. on coal (anthracite, pea and smaller sizes), carloads minimum weight marked capacity of car, except that when car is loaded to full visible capacity actual weight will apply, from Le Roy to Buffalo, \$1.76 per ton. The new rate became effective Nov. 1, 1924, P. S. C. No. 2022.

The commission also has approved the tariff of the New York Central R.R. (East) on coke, coke breeze and coke dust, carloads minimum weight in open cars 50,000 lb. (except that when car is loaded to cubical or visible capacity actual weight will apply, but not less than 35,000 lb.) and in box or stock cars 40,000 lb., from Buffalo, East Buffalo and Harriet to Green Island and Troy \$2.90, a reduction of 50c. per net ton. The rate becomes effective Nov. 28, 1924. Sup. No. 1 to P. S. C. N. Y. C. No. C-148.

### Indiana Rate Order Modified

Modification of the order in the matter of Indiana rates, so as to except from its provisions certain intrastate rates applicable between points in Indiana, has been ordered, upon rehearing, by the Interstate Commerce Commission. The modification is as follows:

"We are of the opinion and find that the rates and charges for the transportation of coal from mines in the Linton, Brazil and Princeton districts in Indiana to Irvington, Ind., and from the Linton district to Putnamville, Ind.; for the transportation of coke from Indianapolis, Ind., to Irvington; and for the transportation of straw, in carloads, from Veedersburg, Hillsboro and Layton, Ind., to Marion, Ind., in effect on Jan. 28, 1921, did not cause any undue or unreasonable advantage, preference, or prejudice as between persons or localities in intrastate commerce, on the one hand, and intrastate or foreign commerce on the other, or any undue, unreasonable, or unjust discrimination against interstate or foreign commerce. Our order will be modified accordingly."

### C. & O. Lowers Through Rates To Northwest

New and lower rates to approximately 2,100 points of destination in the states of Iowa, Kansas, Minnesota, Missouri, Nebraska, North and South Dakota are to go into effect on Dec. 5 on the Chesapeake & Ohio Ry., according to an announcement just made by A. M. Dudley, general coal freight agent of that road. The changes were made to meet those now in effect from points on the Louisville & Nashville R.R. Among some of the rates to representative points from mines in the New River field are the following: Cedar Rapids, Iowa City, Marshalltown, Ames, Des Moines, Waterloo, Iowa,

\$4.68; Clinton, Iowa, \$4.32; Council Bluffs, Iowa, \$5.53; Omaha, Neb., \$5.53; Mason City, Iowa Falls, Iowa, \$5; Sioux City, \$5.97; Winona and Rochester, Minn., \$5.09; Mankato, Minn., \$5.15; Springfield and Minneapolis, Minn., \$5.55; Marshall, Minn., \$5.62; Ghent, Minn., \$5.87; Porter, Minn., \$6.08; Watertown, S. D., \$6.14; Pierre, S. D., \$7.23; Aberdeen, S. D., \$6.56; Houston, S. D., \$6.73; Oakes, N. D., \$6.93; Kansas City, St. Joseph and Dearborn, Mo., \$5.53; Bettendorf, Muscatine and Davenport, Iowa, \$4.20; Ottumwa, Iowa, \$4.56; Leavenworth, Kan., \$5.53; Waterloo, Iowa, \$4.68. Rates from the Kanawha district to the points mentioned are 15c. a ton less.

## Obituary

**J. F. Healy**, chief engineer of the Hutchinson-Island Creek Coal Corporation, of Omar, W. Va., died suddenly Nov. 1 at Omar. He was born in Blossburg, Pa., sixty-four years ago and was a graduate of Pennsylvania State College. For many years Mr. Healy was connected with the Davis Coal & Coke Co. and for a time was general manager of the Davis Colliery Co. For a time he was allotment commissioner of the Chesapeake & Ohio, afterward becoming connected with the Main Island Creek Coal Co.

**Charles D. Junkins**, secretary of the Monongahela Coal Association and long identified with the business life of Morgantown, W. Va., died at the county hospital at Morgantown within 24 hours after suffering a cerebral hemorrhage at his office. Mr. Junkins, who was 60 years of age, was a native of Randolph County but had been connected with various enterprises in Morgantown for a period of more than 20 years. He also was manager of the Morgantown Brick Co., and secretary of the Morgantown Country Club. At one time Mr. Junkins was associated with the late John A. Clark of Fairmont in the coal business. A few years ago he was identified with the North American Coal Co., continuing with that concern until it was absorbed by B. M. Chaplin and associates.

An unusual career was brought to a close with the passing of **Dr. Bruno V. Nordberg**, founder of the Nordberg Manufacturing Co., Milwaukee, Wis., whose death occurred Oct. 30, at the age of 67. For more than forty years he was closely associated with engineering progress in the power and mining machinery fields. He was born in Finland in 1857, was graduated from the University of Helsingfors in 1878 and came to this country in 1880.

Death recently claimed **W. G. Robertson** of Scranton, Pa., who was prominent in coal mining circles here for almost 50 years. In that time he served as a mine foreman, engineer, coal operator, etc. For a time he also was Director of Public Works in the city of Scranton. He was buried at Dunmore, Pa.

## Coming Meetings

**Illinois Mining Institute**. Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

**American Society of Mechanical Engineers**. Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**West Virginia Coal Mining Institute**. Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**Coal Mining Institute of America**. Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

**West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers**. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

## New Equipment

### Precalced Cast-Iron Pipe

Two features differentiate the cast-iron pipe manufactured by the McWane Cast Iron Pipe Co., of Birmingham, Ala., from the standard product. The first is the fact that small sizes—1½-, 2- and 3-in. pipe are made; second that all pipe has precalced joints.

The precalced joints greatly increase the ease and speed with which the pipe is connected, and eliminate the need for tediously pouring lead joints in the field, a job of no small dimension where the pipes are small and their lengths short. It is stated that this combination of bell-and-spigot joint, factory-

Can Install This Cast-Iron Pipe with Little Labor

By having most of the joint formed at the factory this cast-iron pipe may be easily put in position on the job. This is an important detail when rapid progress must be made, especially in cold weather.

made, with short lengths of pipe cast by the McWane green-sand process, overcomes the difficulty occasioned by the brittleness and lack of flexibility of small cast-iron pipe lines.

This small pipe, offering the high resistance of cast iron to the corrosive action of soil, water, and acids already has been used extensively by many mines and industrial establishments in place of wrought-steel or iron pipe.

In the 4- and 6-in. sizes the pipe is made in standard 12-ft. lengths. These sizes, too, are equipped with the precalced joint which is made about a mandrel while the pipe is in a vertical position. The mandrel, being slightly larger than the spigot end of the pipe it represents, provides ample clearance for entry of the latter. In the order named, braided jute, a specially-prepared ring of iron wedges embedded in lead, two more braids of jute, and a final filling of molten lead, are placed in the pipe bells around this mandrel. What will be the lower half of the joint circumference is then precalced.

Fig. 1 shows the precalced side downward. Driving the lead in at the top forces the pipe down to a firm seat at the bottom, and a positive joint results.

It will be observed that this is not

#### Materials Used When Making the Precalked Pipe Joint

For gas joints an extra lead ring is supplied. It can be slipped over the spigot end of the pipe and forgotten until the joint is completed in the regular way.

simply a lead joint, but a combination lead-and-jute joint. The quantity of lead is gaged so that the force of the blows in calking extends through the lead to the top jute and thence through the wedges to the bottom jute, the latter being forced by the wedges into the groove shown at the base of the bell. This gives three points at which the water or gas is held, the bottom jute, the top jute and the lead.

The function of the wedges is not only to carry the force of the blow from the top to the bottom of the joint, thus insuring tightness and rigidity, but also tighten automatically the joint materials in case of external stresses that might tend to deflect the line. When such stresses occur the end of the pipe 4 at the joint subjected to strain tends to go down and the point at 1 tends to come up. The compressed jute at the bottom of the bell resists this tendency, but if the strain should be such as to deflect the joint slightly the bottom jute will be further compressed and will force back the wedges at the bottom of the joint, 3, thus compressing both layers of jute at 2.

Laying precalked joint pipe is therefore a process of finishing, rather than making, the joints. The calker is the first and only man needed after the spigot end is slipped into the pipe bell. The lead-pourer, yarker and bell-hole digger are not needed, all their work previously having been done by the manufacturer, and the joints delivered ready to calk. It is estimated that the labor of two men is saved in the average pipe-laying job.

#### Put the Little Hoist Where Headroom Is Low

The Lo-Hed mono-rail electric hoist, designed and built by American Engineering Co., of Philadelphia, is a general purpose hoist with a number of important and exclusive features.

It differs radically in design from other electric hoists. An outstanding feature is that it is claimed it operates under low head room. The motor and drum are arranged on opposite sides of, and parallel to, the I-beam rail and the load block can be drawn up between them, into the body of the hoist until it practically touches the bottom of the rail.

The space taken by the 1-ton plain trolley hoist under the beam is only 10 in. while the 3-ton plain trolley requires only 14 in. As a result the hoist can be used in many places where other units could not meet the head room conditions, especially where ceilings are low, bulky loads are handled,

obstructions must be cleared, or where large size pieces must be placed on machines and trucks.

Another important feature is the complete and easy accessibility of all working parts. By simply removing the outer covers, which can be done in a few minutes, all parts of the hoist can be inspected, and, if necessary, any part can easily be removed. The motor, for example, can be taken out in a few minutes without disassembling

of standing up under the severest conditions to which a hoist can be subjected. Only the best materials and workmanship are used. All gears are of drop forged steel. Positive automatic lubrication is provided. Hyatt High-Duty bearings are used on all gear shafts and the trolley wheels, thus reducing friction to a negligible quantity. Automatic lowering brake, of drop forged steel, holding brake and upper limit switch combine to assure safe operation at all times. Brakes take effect instantly, stopping the load without drift and affording unusually sensitive control.

The complete unit has a mechanical efficiency of over 80 per cent and a factor of safety of at least five at full load.

It is built in sizes of 1,000 to 12,000 lb. capacity. There are five types for either a.c. or d.c. The first four types are arranged for operation from the ground. The various types are as follows: (1) Bolt suspended, (2) plain trolley, (3) hand-geared trolley, (4)

#### Phantom View

Because the hook of this hoist can be nearly bumped against the I-beam it can be used in places having low head room.

the main frame or body of the machine, and either with or without a load on the hook.

In addition to these features the hoist is built with the idea of making it a quality piece throughout, capable

motor-driven trolley, (5) cab controlled, motor-driven trolley, with either open or inclosed cab.

Two or more hoists can be hooked up in tandem and the capacity increased accordingly.

#### Motor-Driven Trolley Type

Maximum service and utility of space is obtainable with a hoist which can lift and carry material close to the roof. Cabs for both indoor and outdoor service keep the operator out of rain and cold.

## Our Wasteful Railroads

**F**EW consumers of coal are more wasteful than the railroads. It would be difficult to make a coal operator wax eloquent on this defect. He is apt to regard this trait as a virtue and to keep silence lest the railroads should be spurred to action or their inveterate enemies should force them to it.

But perhaps the operators would feel more disposed to advocate a measure of economy if they believed it would help rather than injure the coal industry. The railroads, if they introduced stokers, or pulverized-coal furnaces, could be converted into users of fine coal. In doing this they would aid the coal companies by increasing the market for screenings.

Here lies one of the largest outlets for fine coal—an outlet that so far has never been developed. The change would be so beneficial to the railroads and so much less revolutionary, expensive and questionable than electrification that it would seem they should easily be induced to consider it. We commend this matter to the consideration of the Research Committee of the National Coal Association, which, we believe, is looking for opportunities for the marketing of screenings and to the anthracite companies which find the disposal of fine coal a difficult problem. What a blessing it would be to the latter if the railroads that have ceased to burn anthracite or are now using an excessive quantity of soft coal would return to the fuel they once burned, consuming however, the finer sizes that are now a drug on the market. The public utilities have blazed the trail that leads to the use of fine coal. Let the railroads follow it.

## Briquetting Incombustible

**M**UCH wonder has been expressed that briquetting as a process has been so slow to justify itself. The exact reasons are not quite clear, but there are many that might be advanced. Some of the briquets are not durable. They are not waterproof and they soon fall apart. Most of them are made from fine coal which usually contains a large percentage of incombustible material. Washing of this coal when the attempt is made in a crude way is extremely wasteful, and there is a big waste of good binding material in briquetting so much rubbish with the pure coal. Moreover, the public when it gets the briquet not only has a fuel with a low heat content but finds that it has an unusual ash nuisance with which to contend.

Today, we record a commendable effort to present the public with an unusually pure briquet having a binder of real fuel value, and it will be seen whether it makes the headway on the market that its sponsors have reason to anticipate. If it does it will either sweep the field or induce briquetters to pay more atten-

tion to the importance of washing coal before briquetting it.

The domestic consumer may have an extremely hazy notion as to effect of the freight paid on incombustible on the cost of running a furnace. He may not realize just how much he is hampered by the presence of ash. He may not sense its effect in causing a loss through unburned coal. But he has a keen perception of what is the aggregate cost of maintaining his fire, and he is actuated by that perception, with the result that he will ultimately turn where the best results are obtainable.

The selling of coal, briquets and oil is subject to modes like the fashions, but in the end, after many jumps in the dark, the consumer will alight and will stay where he is convinced that his interests are best served, no matter how persuasive may be the salesman who for a brief while reaches his ear and obtains his nimble dollars.

## The Unsafety of Safety Lamps

**D**AN HARRINGTON'S article on the safety lamp and its dangers, contained in our issue of Oct. 30, must have raised in many minds a question as to the inherent safety of such lamps. It is interesting to note, however, that all so-called failures of safety lamps in this country have been shown to be due to their being in what the U. S. Bureau of Mines would term unpermissible condition. They were key-locked lamps which the mine examiners or others had taken apart in the mine to relight or else they were improperly assembled and would not have passed any of the simple examination tests of a well-instructed lamphouse tender.

This much, however, is certain: The lamps were the cause of the disasters enumerated, and Dan Harrington is justified in regarding that form of equipment as unsafe if in its use disasters frequently occur. Why they occur is only a matter of importance if we, knowing how they happen, can prevent their recurrence. The ugly feature is that we have known how to forestall them for so many years and still the accidents happen. We want a device that does not contain this menace, if we can get it.

The electric lamp is safer than the closed flame lamp, but it does not show the presence of gas. Consequently with it men will continue to work in a dangerous atmosphere. Their work would be quite safe so far as the electric lamp is concerned, but as there are many ways in which gas can be exploded it is necessary that the workmen should be warned, and speaking broadly: How shall one operate a gaseous mine without a flame safety lamp? There are ways of testing gas, more accurate and certain than the lamp affords, but they are slow and not as simple. We may, however, have to adopt them.

## Alternating-Current Locomotive Haulage in Mines Must Wait

**S**IGNIFICANT to the future of electric traction in the mining industry are the locomotives for which the New York, New Haven & Hartford R.R. Co. has recently placed its contract. Though they receive alternating current from the transmission lines they are actually driven like their predecessors by direct-current motors. These railway locomotives contain their own voltage-reducing and power-converting substations.

They are equipped with a transformer for lowering the 11,000-volt, 25-cycle, single-phase current to 2,300 volts and with a synchronous motor-generator set to convert that current from alternating to direct. The traction motors are of the direct-current railway type as are those at the coal mines. The direct-current generator which delivers current to the traction motors is designed with a variable field, and the speed of the locomotive is regulated by the field control of the generator.

So despite all the advance in electrical matters the traction motors are still of the standard series direct-current type similar to those used in coal mines. It appears, therefore, that the coal operator has the equipment that is best suited to his needs and indeed that which fits best all traction equipment.

Evidently though the electric haulage of the far-off future may be by self-contained storage-battery locomotives, those which are operated from power lines will probably continue to use direct current.

## Why All This Ado?

**A**LBERTA and British Columbia have a wealth of coal—good coal—and Canada in all its central provinces has none. It is pathetic to notice what a complex this has created. In the United States it would be said: "It's magnificent coal but what use is it? Leave it where it is. In twenty or thirty years it will be valuable perhaps. Meanwhile we will mine it for local use. It is not wealth at present but it will be in time." The U. S. Geological Survey would calculate its extent and its thickness, put a price of \$60 to \$600 an acre on it according to its purity, quantity and depth, write a bulletin or two about it and everyone would forget it.

But when it is in Canada that is just what Canada cannot do. Everyone proceeds to open it and clamor because it cannot be transported to the distant markets of the country. The operators suffer from the insurmountable obstacles and look to the government to help them out of the economic blunder they have made. The investment looked like patriotism to them, but was it? They sought to fill a need that did not exist. A mine without a market is as unprofitable as one without mineral.

The frontier of manufacturing moves slowly. As Mr. Geddes recently remarked in these pages: All would have been well if Columbus had discovered Vancouver instead of San Salvador. The march of empire would have moved eastward and Utah, Colorado, British Columbia and Alberta would have been leading manufacturing centers, and farmers would be breaking new farms in Quebec, Vermont and New Hampshire.

But unfortunately for the West, Vancouver and the Golden Gate were discovered later, and so the roping

of steers is being done in British Columbia and Alberta, in Colorado and Utah rather than in Ohio. Facts are facts and as a result the Western coal fields in Canada and the United States will continue to have scattered development. Why make, therefore, so much fuss? Coal is not coal where distance prohibits its mining.

## Breaking Down Bone Coal

**W**HAT TO DO with middlings, the coal that is high in ash but has fuel value, is one of the difficult problems of the coal operator, the more because so many companies are now buying power and can no longer solve the problem by using this inferior coal in large measure in their own power plants. In fact, it is the irony of fate that the central station came into active being just as the operator was beginning slowly to learn that he should use the middlings and the pyritic coal for his own needs. He began to buy power just too soon to learn what a wealth of opportunity existed in his unsalable coal. If he had taken earlier to stokers and pulverized fuel he might not have succumbed so readily to the blandishments of the power salesman.

What now should he do with his middlings or bone? We will not say he should invariably crush and clean them. Whether in any particular case the middlings should be disintegrated by crushing and an attempt be made to set their good coal free much depends on the character of the material thus offering itself for treatment. If the crushing fails in any large degree to break apart the coal and the ash because their admixture is intimate, crushing and cleaning will not help him. If the price of cleaned fines is too small to pay for treatment, with interest on the equipment and payment for depreciation plus a small profit, he cannot be recommended to make the attempt especially seeing that these operations reduce the tonnage. But if he can obtain by this method a fuel for which the market is greedy as is the case of the producer of a coal used extensively for stokers—a low volatile product—he is justified in preparing it and indeed may be well advised if he increases the percentage of middlings including in them the "off-color" coal that he has been putting in with that of greater purity, thus decreasing its marketability and possibly its price.

It is a matter for careful consideration and for test. One is foolish to dogmatize. It would be better to construct, as a metal-mining company would, a pilot plant that would indicate what might be attained by a truly commercial operation. Some companies, at least, should find the practice highly profitable, and we look for it to become more general.

However, care must be taken to clean the fine coal in a plant so constructed that it will not waste the crushed coal by its inefficient operation or by letting the cleaner coal pass away as discolored water. The inability of some jigs to clean fine coal and the unwillingness of the market to accept the product and, what is the same thing, its inability to use it has prevented this crushing in the past. Time has changed this condition. Some users, particularly those that pulverize coal, prefer the fine sizes, and washing facilities have improved. Consequently we look for progress in this direction, especially in the South, where even in the depth of their winter season the coal will not freeze in the car. In the North dry preparation would obviate the disadvantage inherent in wet coal.

## V-Panel Mining Progressing in Southern Colorado

West Virginia System Minus Conveyors Is Transplanted to Boncarbo Mine of American Smelting & Refining Co.—Tracks Are Kept Parallel to Faces in Each V—Roof Gives Trouble but Cost of Coal Is Cut

By E. W. DAVIDSON  
Associate Editor, *Coal Age*,  
Chicago, Ill.

**M**INING by the V-system has caught the imagination of almost every coal-producing company in this country. Many companies have studied its possibilities as applied to their own conditions, but only a few have actually gone underground and tried it out. One of the few is the American Smelting & Refining Co. with a coal mine at Boncarbo, Colo., a few miles back in the hills from its coking plant at Cokedale in Las Animas county.

There, for nearly a year, the V-system has been on trial; not with conveyor transportation of coal from the face, as in Everett Drennen's original V-system installed in the mine of the West Virginia Coal & Coke Co. but with cars and tracks. Many obstacles have arisen, some of which have not been overcome; but, in the words of H. H. Bubb, general superintendent of the mine and the coking plant, "considerable economies of mining have been effected, and we are going ahead with the work." If the system works well enough, the use of cars probably will be continued, as 1,200 tons a day is all the company wants to produce at present, but if conveyors are considered necessary they will be installed later.

The Boncarbo mine is a comparatively new property upon which the company relies for coal to supply its 350 beehive coke ovens at Cokedale. The mine now employs between 250 and 300 men. The thickness of the coal varies from 4 ft. 6 in. to 5 ft. 6 in. and is comparatively free of dirt partings. The mine has six locomotives for gathering and one for main haulage

and has one of the best systems of heavy trackage in the West.

The experiment in V-mining started in the Boncarbo mine in March, 1924. Mr. Bubb and his mine superintendent, C. R. Garrett, had visited the Norton mine in West Virginia to see the original American V-system there, and other engineering talent had been devoted to the problem of transplanting V-mining to Boncarbo. The plan adopted was almost identical with that used at Norton except that no conveyors were installed.

The start was made in a piece of coal on the first left off the main west. This location was chosen because mining in that territory by the usual room-and-pillar method had reached that particular coal, and also because it was reasonably close to the outside and therefore handy for inspection.

### PIONEER WORK REQUIRED MUCH TIME

It was decided to work three blocks at once in this initial panel, thus providing six working faces. Three entries, 8 ft. wide and at 80-ft. centers, were driven up 300 ft. to a barrier pillar and then widened out to form three V's on 45-deg. angles. This pioneering took a good deal of time and had all the other disadvantages of narrow work, but it eventually opened up the six faces, each approximately 90 ft. long.

Tracks were laid in each entry with a switch at the throat of each V, two lines of track diverging from the switch to parallel the faces. The face tracks were laid 6 ft. from the coal and were moved after every

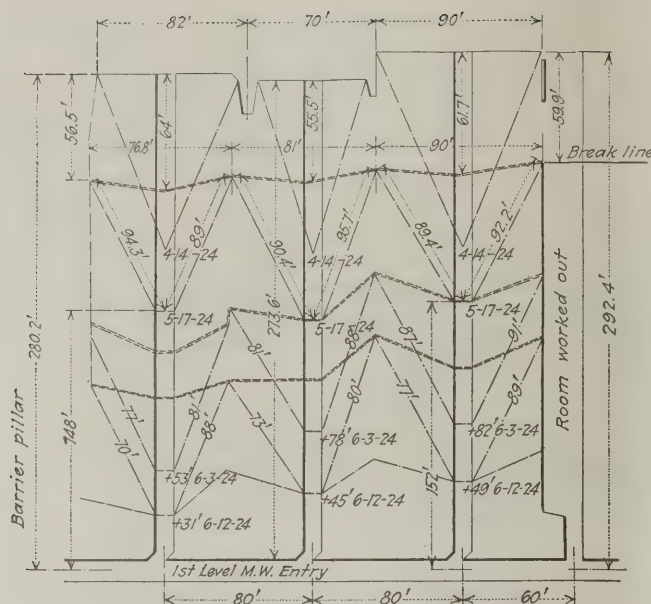

Fig. 1—Boncarbo Mine's First V-Panel

This was started in March, 1924, and was worked in stages shown by the progress dates entered at the throat of each V. The cross entries leading back from each V were spaced on 80-ft. centers but the angles of the V's were not uniform. The first effort was to break the roof in a straight line. This did not work so well and break lines thereafter were angled slightly to conform to the V's with better luck.

second cut had been loaded out. On each of these tracks as many as eight cars could be spotted at one time, but in practice this number varied from six to eight.

The crew working the trial panel was composed of seven company men and fourteen loaders. The seven company men comprised two trackmen, two timbermen, one machine runner, one helper and one shift boss. The twenty-one men includes every one working in the V-section except the driver of the gathering locomotive. Their efficiency improved greatly after they had been at the work for several weeks, proving that V-mining requires more than good engineering plans to operate successfully. The men doing the actual labor require some training, and much talent is necessary to co-ordinate the activities of the various groups.

It was planned that one mining machine should cut the two faces of one V each day, while the adjoining V was being loaded out by the fourteen men of the shovel crew. Simultaneously, the third V, which had

Fig. 2—How Chain Pillars Were Drawn by V-Mining

This illustrates the method followed in the triple entry that had been opened along one side of the second territory that was converted to V-panel mining, in the Boncarbo mine.

been cleared up the preceding day, was being worked by the timbermen and the track gang. Thus the three divisions of the crew rotated from V to V.

This plan, of course, made no provision for simultaneous driving of the narrow entries to prepare in advance for V-mining in any other block of coal. However, the ordinary cutting machine can cut so much more than 180 ft., which was a days' assignment for the Boncarbo machine, that the machine runner and his helper might also have driven entry with a short-wall machine had opportunity been provided.

#### LARGE DAILY OUTPUT PER UNDERGROUND MAN

The coal in the V-panels was undercut with a machine having a 7½-ft. cutterbar, each cut being of an average depth of 7 ft. During the whole period of about two months which was devoted to this territory, an average cut provided 126 tons. It was possible for the mining machine to make two cuts per week on each face so that the output of the six faces, when they were working every day, averaged 1,500 tons per week.

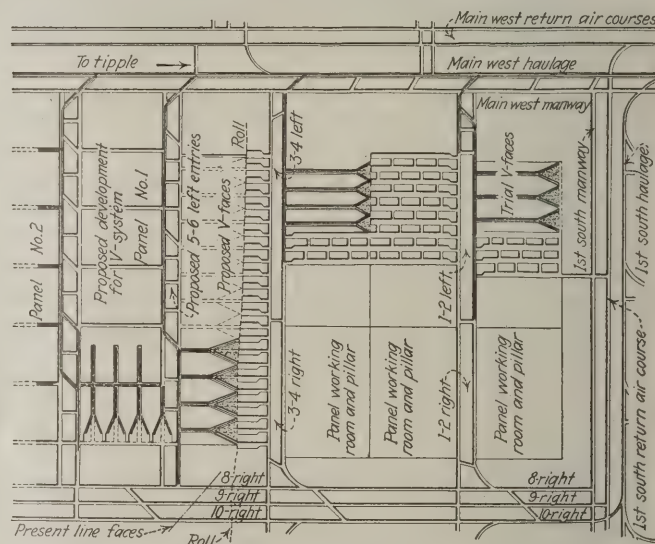

Fig. 3—This Is Boncarbo's Eventual Plan

If the mine is converted to V-mining completely, territory will be opened up probably to the barrier pillar of the nearest main entry, as shown here, with V-faces in panels retreating. A 12-ft. roadway will lead back from the throat of each V to laterals cutting the panels every 300 ft. These deliver coal to a heading at the inbye side of each panel. The chain pillar in this heading is cut back by a V-face kept in line with the rest of the panel operation.

The exact average per loader was 17 tons daily, but considering that there were twenty-one men working the territory and getting out approximately 1,500 tons a week, the daily output per underground man would be 12 tons. This is materially better than the average daily output per underground man in the mine on a room-and-pillar basis, which for a year has been wavering from 4.7 tons to 5.3 tons.

However, the V-system encountered difficulties from the start. In the first place the 8-ft. entries were so narrow that the throats of the V's were choked. There was insufficient width for placing the switches and to permit the machines to sump in. So it became necessary to round off the throat when each cut was made. This was overcome in later operations by driving up the entries 12 ft. wide instead of 8 ft.

As might be expected the roof afforded another important difficulty. The coal was immediately overlaid with draw slate ranging in thickness from 3 to 4 ft. This would come down without difficulty but above

it was a heavy sandstone stratum which would not break "according to Hoyle." The worked out area produced by the retreat of the three V blocks was approximately 240 ft. wide. This was too great a span for the sandstone. It was not strong enough to support itself firmly, and it was too strong to come down at the break lines.

The plan was to bring down the roof after each 50 ft. of retreat. When the first 50 ft. had been mined out a single row of timbers set skin to skin was erected in line with the points of the V's. But the roof would not cave at this line. It crushed the points of the V's and some coal was lost. So a stronger double break line was constructed, using 4x5-in. cap pieces 4 ft. 6 in. long. The two parallel lines of props under these cap pieces were 3 ft. from center line to center line. The line was no longer built straight across the room, but was bent in at a slight angle toward the throat of each V. This system was only moderately successful.

Then the break line was erected at 80-ft. intervals instead of 50-ft. The worked-out area was kept timbered stoutly until the full 80 ft. of depth had been attained. Then, with the double break line in place, the forest of props beyond it was pulled, with the idea that a cave would thus be made inevitable. In one attempt 636 props were removed, and the area left unsupported, but nothing happened.

After waiting for a time without result, a new type of break line was constructed with the idea of protecting the points of the V's when the roof finally should come down. A triple line of timbers was set skin to skin and this today is counted on to produce breaks at the desired places. Timbers are used liberally in front of this triple line to hold each roof area until the coal faces have retreated a safe distance. Then these props were pulled and the break line is expected to produce results. Much timber is used in each V between faces also. The timbermen are expected to keep the front row of props within 6 ft. of the coal.

Each time the face track is moved, it is laid inside the front row of props but before the second fall is loaded, new timber has been set between the track and

Fig. 5—Prop Yard at Boncarbo Is Well Stocked

But in spite of this heavy storage of timber it is a fact that in those sections of the Boncarbo mine where V-panel mining is in operation, the timber cost per ton of coal is "several cents" less than it is in the room-and-pillar territories.

the coal and loaders must shovel through it. This is not regarded as a serious handicap, however, and does not materially reduce the speed of loading.

Although the appearance of the territory being worked by the V-system gives the impression that much timber is necessary, the fact is that the cost of timber per ton of coal produced is several cents under that incurred in the main body of the mine where the coal is removed by the room-and-pillar method.

The roof difficulty was such that in the new areas now working the V-system, panel entries are laid out on 60-ft. instead of 80-ft. centers so as to reduce the distance between V points thus decreasing the roof pressure on each. The angle of each V is narrowed down also in order that the faces may maintain their full length of 90 to 100 ft. This does not obviate all roof trouble, but it has reduced it greatly, and the operators hope that the method will work successfully throughout the mine in case the whole mine is worked on the V-system.

The effort now is to finish out territories that are

FIG. 4

#### Coal from V-Panels Reaches Tipple

Heavy double main-line trackage steadies the movement of coal. When a trip reaches the tipple, it is coupled to the end of the string of loads standing there. A car haul feeds the loads to the dump. Empties are delivered by a kick back to the tail end of a string of waiting empties. From this string the main-line locomotive takes its empty trip. Overhead construction is made permanent by the use of steel rails for poles.

**Fig. 6—A Clean Yard Bespeaks a Well-Ordered Mine**

This yard with the repair shop at the right and a storage building at the left, gives some idea of the orderliness which prevails throughout the Boncarbo mine. "Spick and Span" are two of the best employees Mine Supt. C. R. Garrett has. The yard tracks are carefully laid out and kept in alignment.

partially worked by room-and-pillar so that unworked areas can be laid out for V-faces only. When that time comes, if it ever does, the active areas will be operated in panels each 250 ft. wide and 1,500 ft. long (Fig. 3). V's in sets of four to each panel will be started at the boundary and retreated. An entry 12 ft. wide leading back from each V will connect with lateral entries cutting each panel at intervals of 300 ft. The 12-ft. roadways will be kept driven back far enough so that laterals can be discarded and wiped out by the retreating V's, the haulage from each V being carried back through the new roadway to the next lateral. Chain and barrier pillars are taken simultaneously with the panel coal so that theoretically at least, extraction is complete.

In spite of the troublesome roof and other obstacles and without the conveyor which has helped to make the Norton, W. Va., mine famous, the Boncarbo mine already has shown that V-mining can be made profitable if it is intelligently done. In the Boncarbo system, the ratio of miners to company men is only 2 to 1, whereas in room mining throughout the rest of the property it is 4 to 1. However, this is no certain

indication of the reduction that could be made in the force of men necessary to get out the 1,200 tons daily that the mine must produce. It is difficult to figure what additions to company men would be necessary if the whole mine were on a V-basis.

However, it is definitely proved that coal from the V-panels has been produced at somewhat less cost than coal from the rest of the mine and that a given tonnage certainly can be mined out of a much smaller area than has ever been obtained by any room-and-pillar system, with most of the advantages that are to be had from concentration of operation. And judging from the company's experience, its production can be handled readily with cars instead of requiring face conveyors. Whether the Boncarbo system of roof control is sufficiently dependable to justify conversion of the mine to V-mining remains to be determined. But at least the men of the mine have proven that V-mining has its possibilities outside of Norton, W. Va.

## Mine Car Built in Less Than 3½ Hours

BY O. F. TAYLOR

Superintendent, The Elm Grove Mining Co.,  
Laferty, Ohio

In the July 31 issue of *Coal Age*, p. 154, appeared an account of the feat of Joseph Martin of the New River Co., Whipple, W. Va., in building a mine car in 5 hr. 8 min. At 8 a.m. on Oct. 30, George Hess of the Elm

**The Car and the Man Who Built It**

This car is of about 2½ tons capacity. It is of the well-known 3-belt type such as is used in thousands of American coal mines. In fact there is nothing unusual about this car except the time required in its construction.

Grove Mining Co., Laferty, Ohio, started building a somewhat similar car and at 11:25 a.m. had it completed. The work on this car thus required 3 hr. 25 min.

All the material entering into the construction of this car was collected and assembled in the above time, Mr. Hess doing all this work himself with the exception of sawing the ends from three planks each 3x12 in. and 9 ft. long. These were held by the blacksmith Andy Kovach while their ends were shaped with a saw by Mr. Hess to receive the bumper irons.

In building this car 143 holes were bored and an equal number of bolts and nuts employed. The capacity of this type of car is approximately 4,500 lb. Mr. Hess is 58 years of age and weighs about 250 lb. He has been employed by the Elm Grove Mining Co., Oco Mine, Laferty, Ohio, as car builder and repairman for five years. The accompanying illustration shows the car and its builder.

**FIG. 7**

### The Men Who Run Boncarbo

At the right in a white shirt is H. H. Bubb, general superintendent of the mine and the 350-oven beehive coke plant of the American Smelting & Refining Co. at Cokedale, Colo., five miles away. With him is C. R. Garrett, mine superintendent.

# Plant in Newark Makes Briquets by Trent Process

Uses Screenings and Sweepings from Anthracite Yards—After Pulverization Coal Is “Amalgamated” with Oil Forming Pellets Reducing Ash Over Sixty Per Cent—“Amalgam” Is Then Briquetted—Advantages and Uses of Product

BY FRANK H. KNEELAND  
Associate Editor, *Coal Age*  
New York City

ONE OF THE treatments designed to remove a large portion of the ash contained in raw coal is known as the Trent process. A small plant but one nevertheless of commercial size operating on this principle and intended for treating anthracite yard screenings, culm, silt and the smaller steam sizes has been erected recently in Newark, N. J. The Trent process proper aims at material ash reduction, but this plant in Newark will eventually go much further and briquet the purified product, making it into an excellent domestic fuel in many respects superior to the best prepared anthracite.

Naturally, in the vicinity of such a center of population as New York City, where much anthracite is burned, a large quantity of screenings is available. It is the intention to utilize this material, which is both abundant and cheap, in this plant, which is being operated by the Superfuel Corporation of New York.

At present coal-yard screenings are being delivered by barge to the plant, which is situated on the bank of the Passaic River. Upon entering the plant the raw material containing from 18 to 30 per cent of ash is passed through a rod mill by which it is pulverized. The mill is fed by means of a spiral segment of pipe attached to the mill trunnion and revolving with it. At each revolution this dips into a tank or box containing coal, scoops up a certain quantity of it, and delivers it to the mill.

## PULVERIZED MATERIAL ENTERS AMALGAMATOR

After leaving this mill, the ground coal is passed to a Dorr classifier which removes the coarser material, returning it to the rod mill for regrinding. Fine material or that small enough to pass a 100-mesh sieve is flushed from the classifier to the churn or amalgamator. This is a tank separated into several interconnected compartments by suitable partitions or baffles. Each compartment is provided with an agitator or paddle wheel, and all are mounted on a common shaft extending the entire length of the tank. The arrangement of baffles is such that the material in the tank passes progressively from one compartment to that succeeding, over one baffle and under the next.

To the mixture of powdered coal and water entering the amalgamator a small quantity of oil is added. The entire mixture consisting of water, powdered coal, powdered ash-forming material and oil is then violently agitated by the paddles.

Under this action the oil will adhere readily to the coal particles but not to those of earthy matter or to the ash-forming constituents of the original coal. Furthermore, coal particles acted upon by oil, when agitated, will coalesce, amalgamate, or agglomerate into nodules or pellets, the size of which vary from that of a small shot up to that of a walnut or small hen's egg.

These pellets of coal amalgam are readily withdrawn

from the discharge end of the amalgamator, elevated and discharged to a dewatering conveyor. After draining on this conveyor they are delivered to another that discharges them to a storage pile. Ash-forming material is readily flushed out of the amalgamator and run to waste.

The pellets of pulverized coal as they come to the storage pile are not hard and unyielding but may be readily crushed in the hand or between the fingers. Though composed chiefly of oil and coal, they naturally contain some water. This gradually dries out upon exposure to the air.

The product of this process, the “amalgam” pellets, may be burned in a boiler furnace without further treatment. This fuel is being consumed under the

Pellets and Briquets as Made at Newark

On the left is shown a pile of raw anthracite pellets as they come from the agitator. In the center foreground are two baked pellets made from Rhode Island anthracite. Behind them is a bituminous briquet from which much of the oil used in the treatment of the coal has been expelled by baking, as well as some of the volatile matter. On the right is a baked anthracite briquet, ready for the market. Such briquets in a domestic fire burn evenly to a fine clinkerless ash.

boilers of the Titan Iron Works, the power station of which adjoins the coal-treating plant.

For utilization as a domestic fuel, the amalgam requires further treatment. To this end it is pressed into briquets by being passed through an extruding machine. From this it is ejected through circular orifices, the material thus forced out being cut to the required length. These pieces are then passed into a Vandergrift retort through a preheating chamber at a temperature commencing at 200 deg. F. and ending at 1,000 deg. F. During this process the oils and other byproducts are extracted.

Briquets made in this manner are hard and waterproof, make a hot, glowing fire, and do not crumble or change shape until they are entirely consumed. The small quantity of ash is extremely fine and no clinkers are formed. When burned in an ordinary stove, the fire may be banked and retained for 24 hours, without any attention whatever. A fire of this fuel also is slightly more flexible than one of raw anthracite, that is, it will respond somewhat more quickly to a change

in draft. The refuse or ash passing through the grate analyzes only 2 per cent of combustible matter. This is only a fraction of the combustible matter usually passing the grate when ordinary coal is burned.

The important characteristic of this process is the fact that the ash in the original coal is greatly reduced. Tests conducted on various coals show a varying degree of ash removal. Thus, treatment of the anthracite screenings in the manner described reduces the ash from about 18 per cent in the raw material to approximately 6 per cent in the finished briquet. Treatment of Rhode Island anthracite reduces the ash from approximately 30 per cent in the raw material to as low as 8 per cent in the pellet or globule, thus effecting the removal of 72 per cent or practically three-fourths of the total inert matter. Treatment of other coals, both anthracite and bituminous, affords results of a similar nature but varying in effectiveness with the ratio of inherent to extraneous ash in the coal treated.

#### MANY FIELDS OPENED BY TRENT PROCESS

Commercially the Trent process of coal purification opens many possibilities, the scope and limitations of which must yet be determined. Thus the pellets may be fired into the ordinary boiler or metallurgical furnace either by hand or by automatic stoker; dried and again reduced to a powder, they may be burned in suspension in air as pulverized coal.

When briquetted coal treated in this manner forms an excellent domestic fuel, being superior both in convenience and in heat content to the raw material from which it is manufactured.

Time alone can determine the extent of the possibilities involved but it will undoubtedly make available large quantities of low-grade and now wasted coals. It is the intention of the Trent Superfuel Co., to proceed immediately with the erection of a large commercial plant in Newark, retaining the present installation as an experimental or "pilot" plant wherein will be determined by actual trial the characteristics of various coals and the details of processing that they must receive.

### Slowing Down Coal to Lessen Breakage

Shaker Screens at Red Jacket Consolidated Coal & Coke Co., Red Jacket, W. Va.

These screens are installed at a tippie on the Mitchell Branch. When the coal leaves the screen and gets on the smooth plate beyond it, it tends to travel too fast and is slowed down by pieces of wire rope hanging from a cross-piece on the screen.

### Consolidation Transmits Power 70 Miles

The power plant shown in the illustration is the property of the Consolidation Coal Co., Millers Creek division, Van Lear, Ky. It is now shut down, displaced by a 70-mile transmission line from the Jenkins, Ky.,

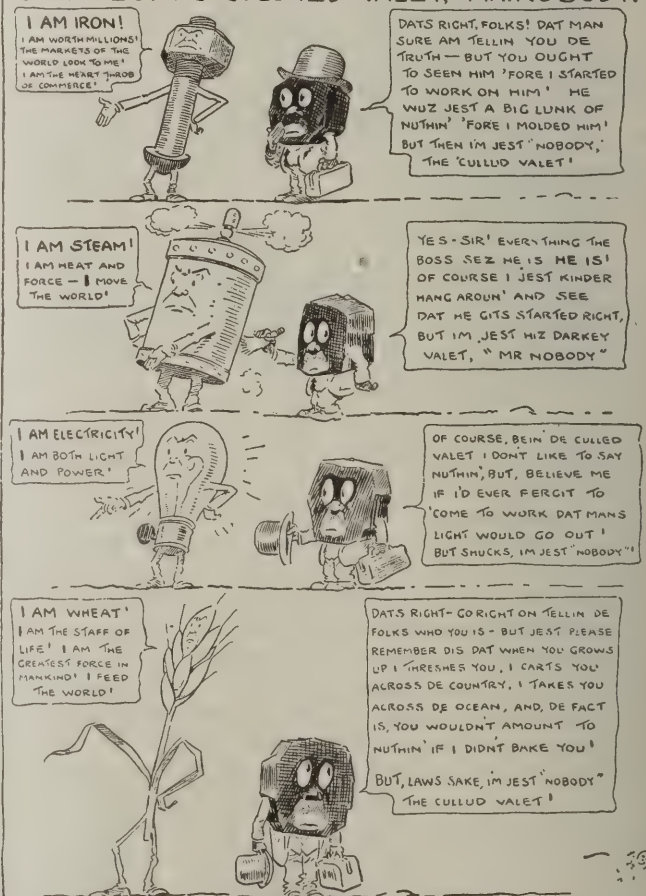

#### Closed This Plant to Bring Power from Jenkins

When the plant became overloaded the Consolidation Coal Co., closed it and brought in power from its Jenkins Mines, the line supplying mines and villages in its course.

plant of the same company. The Van Lear plant was built in 1911. Becoming overloaded, rather than to add to the capacity, the company decided to build the power line, and an arrangement was made with the Kentucky-West Virginia Power Co. to tie into the coal company's line from 6 a.m. till 4 p.m. The Jenkins plant now has 4,000 kw. rated capacity but can carry 6,000 kw. for short periods. The power company furnishes about 9 per cent of the total power that the company uses.

### EVERYBODY'S COLORED VALET, "MR. NOBODY."

#### Introducing "Mistuh Nobody"

Here we have the *Illinois Journal of Commerce's* idea of the service humble coal performs. It is difficult to understand, however, why the creator of this cartoon did not also picture "Mistuh Nobody" as the arch crook robbing the henroost of the householder, and also as the goat of Washington, D. C.

# Controls That Enable Pumps, Hoists and Electric Shovels to Simulate Human Direction

Pump Control Watches Water Level and Shuts Down When Water Is Low — Hoists Automatically Use Power so as to Avoid Electric Peak Loads Which Have to Be Paid for When Power Bills Arrive

BY F. L. STONE

Industrial Engineering Department, General Electric Co.,  
Schenectady, N. Y.

**A**LL MINES must have a drainage system of some sort. In many operations the problem of keeping the mine free from water is one of the most difficult and most expensive of all the many to be confronted. Consequently, we find inside some of our large mines enormous pumping plants, and sometimes the capacity is large enough to supply a fairly large city. The water pumped is usually acidulous to such an extent that in many instances pumps have to be made of special and expensive acid-resisting metals.

Pumps are divided into two general classifications, namely; the multi-cylinder plunger pump and the centrifugal pump. The former requires a moderate-speed motor which is usually geared, whereas the latter calls for a high-speed motor arranged for direct connection. The motor must have moisture-resisting insulation and must be carefully constructed, particularly as to the insulation of its coils.

The atmosphere of an underground pump house is usually humid, and unless special precaution is taken the coils will breathe, taking in moist air which is deposited inside the coils and tends to weaken the insulation. The larger electrical manufacturing companies have designed a standard line of high-speed induction motors for driving centrifugal pumps.

There are no special features connected with the speed of pumps as they are usually run at constant speed until the sump is brought to the required level, after which they are shut down either automatically by means of a float switch or by hand.

Some of these pumping stations have been made fully automatic and arranged so that when the level of the sump rises to a predetermined height, a priming device comes into play which primes the pump. After the priming is accomplished the main driving motor is thrown across the line and the pump started. The main motor cannot start until the pump is primed. Should the pump lose its suction for any reason, the equipment automatically shuts down. The most up-to-

date installation of this sort, is in one of the mines of the Philadelphia & Reading Coal and Iron Co.

The selection of the proper centrifugal pump for a given job should receive careful consideration. Pump manufacturers list the same pumps for various speeds and heads. The efficiency curve of a pump in most cases shows a definite maximum and a rapid falling off either side of this point of highest efficiency. If a

pump is selected to operate at a speed different from that which affords the maximum efficiency, the result, irrespective of the drive, will be an inefficient installation.

In many wet mines we find what are known as gathering pumps which consist of small portable equipments that can be moved about the mine to take care of local flood conditions. These gathering pumps are usually small plunger type units and manually controlled, being driven by an induction motor or a direct-current motor taking power from

## ELECTRICAL WATCHMEN

**E**LECTRICITY used to be synonymous with trouble. If an operator installed electricity he got things done, but only if he continually kept after his electrical problems — and they were many and perplexing. But today the machinery does much of the watching itself, and it fails most and wastes most when left for any reason to the care and judgment of a workman. Automaticity removes the human element. Men are just about as often obstinate and misguided as they are negligent and absentminded. The electric controller is the incarnation of the mind and purpose of the designer and is constituted so that it simply can't be in discord with its master's purpose.

the trolley line or separate circuits for the purpose.

Of all the problems connected with the mine that of the proper selection of the hoist is perhaps the most interesting. Electric hoists have long since passed beyond the experimental stage and have innumerable times demonstrated their greater economy as compared with any other form of hoisting.

The electrical engineer is no longer asked to compare the economy of the electric hoist with that of the steam engine. One manufacturing company has, within the past fifteen years sold 230,000 hp. in electric hoists divided among 450 units. The only problems now to be solved are, How large the drive for the hoist shall be?; What is the best shape to make the drum?; and, finally, What is the best control system for the hoist? The question of size can be readily determined from the duty cycle. This duty cycle can be calculated with great accuracy.

## CYLINDRO-CONICAL DRUM MAY CUT RATING

The best shape of drum can be determined only after several duty cycles have been made using various shapes. In many instances, a plain cylindrical drum is necessary. This is particularly true if hoisting is to

From a paper on "Electricity in Mines," read at Pacific Coast Convention of the American Institute of Electrical Engineers, Pasadena, Cal., Oct. 13-17. Parts of the same paper will be found in *Coal Age*, Nov. 6 and 13.

### When Mines Have Many Cave Falls

During rainy seasons in the anthracite region no Moses' rod is necessary to strike the rocks for water. At some places many of the beds outcrop and it is an easy matter for the water to enter the mines. Even where there is a heavy rock cover the cracks in the cleavage planes permit large volumes of water to enter the mines.

be accomplished from more than one level. The conical drum and the cylindro-conical drum have only a special field of application, but in this field the proper selection of the shape is of quite vital importance. For instance, on short fast cycles the rating of the main-drive motor can be reduced as much as 35 per cent by the use of a cylindro-conical instead of a straight cylindrical drum.

With drums other than cylindrical, the upward moving load is started on the small diameter while the downward moving load starts on the large diameter. This difference in diameters reduces the starting torque materially, and in fast cycles the acceleration is frequently the controlling factor in the motor rating. This reduction of starting torque is therefore of great importance. There are limits, of course, beyond which it is not well to go in proportioning the large and small diameters.

The small diameter is usually fixed by the diameter of the rope. Conservative hoist engineers feel that the ratio of rope to drum diameter should not be less than

1 to 60, otherwise the rope will deteriorate quite rapidly due to the bending stresses. Thus with the minimum diameter determined, the maximum diameter is limited by the weight and consequent  $WR^2$  of the drum. It is easy to defeat the entire object of the drum by running its  $WR^2$  too high.

There seems to be no limit in the steepness of the spiral on which the rope climbs from the smaller to the larger diameter, drums having been constructed where the diameter increases as rapidly as 2 ft. per turn.

### HOIST CONTROLS DESCRIBED IN BRIEF WORDS

The conical and cylindro-conical drums assist also in keeping down the peaks in deep shafts where the weight of the rope is equal to, or as is frequently the case, far exceeds the weight of the material hoisted. By the adoption of the proper drum, the overbalancing effect of the rope may be nicely compensated and the starting load reduced materially.

As for the proper drive and control to use, we have

### Bituminous Mine Pumproom

The Springdale mine of the Allegheny - Pittsburgh Coal Co., Logans Ferry, Pa., makes about 500 gal. of water per minute. Practically all of this water drains or is pumped to a central sump which has a storage capacity of about 2,000,000 gal. Adjoining the sump area is the main pump station, shown here. Two centrifugal pumps, each with a capacity of 1,400 gal. per minute and driven by a 100-hp., 220-volt induction motor raise the water to the surface.

the choice of a single induction motor usually geared to the hoist drum through one set of gearing, or we have the direct-current motor driven from a motor-generator set with Ward-Leonard control, the motor-generator set consisting of a synchronous or induction motor set without flywheel.

Finally, we have a direct-current motor driving the hoist from a motor-generator set with Ilgner control. By Ilgner control, I mean an induction type motor-generator set with a flywheel large enough to prevent objectionable load peaks on the power line. Briefly, this control consists of a motor-generator set as above described and a slip regulator, which, as the load tends to rise above a predetermined value, inserts resistance in the rotor of the induction motor of the motor-generator set thereby holding the torque of the induction motor practically constant.

The load on the direct-current machine may call for

is connected across the collector rings and is cut in and out at the will of the operator by means of contactors operated from the master controller. The control is, of course, equipped with current limits so that the acceleration peaks will not go beyond certain predetermined values, but these peaks are directly upon the power plant, and no type of resistance will reduce them.

#### RHEOSTAT LOSS LOW WITH WARD-LEONARD CONTROL

In other words, acceleration of a given mass is to be accomplished in a given time, and it will require the expenditure of a certain number of horsepower-seconds. The acceleration of the hoist load by this method of control is exactly the same as the acceleration of any other load where a constant line potential is held. Approximately one-half of the energy taken from the line during acceleration will be dissipated in resistance.

#### Automatic Pumps

One of the greatest advantages of automatically operated pumps is the fact that they can be placed in remote sections of the mines and still be depended upon to function properly. In coal beds which are extremely uneven pumphouses must often be located in the solid rock. Here is one such station with two automatic pumps in the Buck Run Coal Co. mine near Minersville, Pa.

a much greater torque than the induction motor will exert. The result is the set will slow down in speed, the flywheel give up part of its energy. As soon as the load is removed from the direct-current end, the induction motor being considerably below synchronous speed will draw sufficient energy from the line to bring the set back to nearly synchronous speed and restore to the flywheel the energy it gave up during the heavy demand. A properly designed Ilgner system will keep the input to the hoisting equipment practically at a constant value, if hoisting is carried on at a constant rate, or it will limit the demand to any predetermined value.

Thus we have two distinct systems of hoist drive, one using a single induction motor of the slip-ring type with the speed controlled by a variable resistance in the rotor circuit. The second system involves a direct-current generator either direct-connected or geared to the hoist drums and a motor-generator set with or without a flywheel for driving the hoist motor. The second system naturally will cost three or four times that of the first. The question naturally arises, Why should the second system ever be used? The answer must be made from estimates of first cost and operating expenses.

The control of induction motor hoists is so simple that it needs little or no description. A large resistance

With the direct-current system using Ward-Leonard control there is practically no rheostatic loss, as the speed of the hoist is controlled by the generator voltage.

On short fast cycles this saving in acceleration losses amounts to so much that the difference in the kilowatt-hours per trip when using induction motor as compared with the Ward-Leonard is sufficient to warrant a large expenditure for the direct-current system.

Further, the direct-current system of control is much more flexible and lends itself a little better to the application of safety- and speed-controlling devices. The direct-current hoist can be run at reduced speeds with no rheostatic losses. This is impossible with the alternating-current hoist. It is impossible to state with any degree of certainty which system is the more economical until a thorough analysis of the problem is made.

Whether a flywheel is used for the equalization of the incoming power depends on two factors. First, if purchased power is used and instantaneous demands are penalized, then a flywheel should be installed. Second, if the hoist is to be operated from a small plant, either privately owned or a public utility, the addition of a flywheel will frequently be of such value in reducing the peaks on the line that even though the plant be small no additional capacity will be neces-

sary. This would not be the case if an induction-motor hoist or a motor-generator set without a flywheel were installed.

Due to the ease of control where the direct-current Ward-Leonard system is used it has been found feasible to install completely automatic hoists. By this I mean, a hoist which can be started from a push button in the morning and will run continuously for 24 hours or longer, without any manual attention.

#### SUITS ITSELF TO IRREGULAR WORK OF SHOVEL

Many coal deposits have been located so close to the surface that they can be obtained by removing the overburden. This system of mining is commonly known as strip mining. Large electrically-operated shovels similar to the steam shovel have been developed for this work. The largest in use at the present time is what is known as the model 350, meaning that the

entire weight of the equipment is approximately 350 tons. This shovel is capable of handling a 10-yd. dipper and has a boom 90 ft. in length. The duty on the motors of an electric shovel is probably the most severe encountered anywhere. They are continually starting and stopping and being subjected to heavy overloads. Notwithstanding this fact the electric shovel is rapidly coming into its own.

Most electric shovels have a motor for each operation, namely, the hoist, the swing and the crowd. These motors are run from individual generators which form part of a four-unit motor-generator set. The control is a slight modification of the Ward-Leonard, the difference being that each generator has a differential series field which limits the current output of the generator to a predetermined value. Thus it is impossible for the operator to abuse the electrical or mechanical apparatus beyond a certain point.

## Powdered-Coal Furnace No Longer an Experiment

Furnace Life Not Shortened When Pulverized Coal Is Used—Well Fitted to Automatic Control—  
Use Rapidly Spreading

THE SERIAL report covering the years 1923 and 1924 of the Prime Movers Committee of the National Electric Light Association, dealing with the use of pulverized fuel carries much of interest to the coal producer, who can by this means make use of much material that cannot be marketed or does not sell at a profitable figure. The mere fact that today the use of this type of fuel is considered when any new power plant is designed is abundant proof of the practicability of powdered coal in power-generating stations. During the past few years many refinements in furnace design have been made, and many of the shortcomings of earlier installations have been overcome. All of this tends toward greater reliability in operation.

Though powdered coal has attracted most attention by reason of its application to large central stations, its value to the small plant should not be overlooked, for it is here that the largest gains in efficiency are possible. This field is receiving much attention, particularly from manufacturers of unit systems, and the results reported in many cases indicate satisfactory improvement.

The report says in part: Adapted to boiler firing several years ago for purely experimental purposes, the use of pulverized coal has today assumed such importance that it is considered in the design of practically every large power station where coal is to be employed as fuel.

Used by itself, or in combination with other fuels, it should lend itself readily to the application of automatic control, this phase of the art already having been developed commercially to some extent. This feature is, of course, especially valuable when utilized in connection with a fluctuating load or with some other fuel supply.

Recent progress in pulverized-coal development has lain chiefly in refinements to existing equipment and in obtaining the most reliable and economical arrangement of apparatus from an operating standpoint.

Fig. 1—Yearly Increase in Area of Boiler Heating Surface Fired With Pulverized Coal

These figures, compiled by the Fuller Engineering Co., show the rapidity with which pulverized coal has been adopted during the past few years. They show the area of heating surface in boilers fired with pulverized fuel either in operation or under construction. They do not show, it should be understood, the horsepower of such boilers.

Probably the most important developments embodied in the newer installations are the water screen, the waste-heat drier and the radiant superheater.

As engineers throughout the country become more familiar with the operation of this type of plant, much of the skepticism attending its use is being overcome, also certain difficulties at first encountered have been satisfactorily solved with the result that its adoption is now considered almost entirely from a financial angle,

Fig. 2—Typical Powdered-Coal Fired Boiler

This particular installation is in the Middletown Station of the Metropolitan Edison Co. Although powdered fuel thus far has been used chiefly in large units it is equally well adapted to smaller ones. In order to avoid rapid deterioration of brickwork, furnace volumes must be made large.

the question of practicability being generally conceded.

As a stamp of approval that such a plant is both efficient and reliable it is necessary only to refer to the number of large companies that are either planning, building or operating central stations of large capacity using pulverized coal exclusively. Chief among these may be mentioned the Trenton Channel plant of the Detroit Edison Co., to consist of 6 sections of 50,000 kw. capacity each, the first to begin operation during 1924; the Cahokia Station of the Union Electric Light

& Power Co., St. Louis, to be built in four sections of 60,000 kw. capacity each, the first of which is now operating and the second is under construction; the third 60,000 kw. unit of the Colfax Station of the Duquesne Light Co.; the 1923 addition to the Lake Shore Station, Cleveland, Ohio, with a boiler plant consisting of four 3,060 hp. units; and the Lakeside Station, at Milwaukee, two units of which are operating, the first consisting of eight 1,333-hp. boilers and the second, now about 60 per cent complete, consisting of eight 1,828-hp. boilers.

#### GROWTH IN USE OF PULVERIZED COAL

The growth in the use of pulverized coal for boiler firing is best appreciated by reference to Fig. 1, which shows the yearly increase in square feet of boiler heating surface starting with 1916 as a base. The most noteworthy feature of this chart is the large amount of boiler surface under construction or contracted for during 1923. This amounted to nearly 70 per cent of the total for the previous seven years.

The question of furnace maintenance, which it was first thought would be excessive, seems to have been rapidly overcome, and today with proper proportioning of the furnace, air-cooled walls and water screens, there is no more to fear from this source of difficulty than there is with the use of stokers. Moreover, it is now becoming evident that the life of the furnace may actually be longer with pulverized coal than with stokers. This no doubt arises from the unusual care that has been expended on the materials used and on the refinements in furnace design.

FAIRBANKS, MORSE & Co. write us that the 100-hp. "kerosene" engine referred to in the M. H. Fies' article of Oct. 23, p. 577, should be revised to read "oil" engine, that company not making a 100-hp. kerosene engine.

#### Utah's Only Shaft Mine

This is the tippie at Castle Gate No. 3 of the Utah Fuel Co., three quarters of a mile above the town of Castle Gate. The famous "gate" of rock can be seen towering in the background. This mine, which is just getting into production, taps a seam 100 ft. below the valley floor. The tippie has a capacity of 1,500 tons a day. It is equipped with shaker screens and loading booms and is built with a wooden frame sheathed in corrugated iron. The mine has an electric hoist.

## Zeigler No. 1 Shaft Breaks World's Coal Production Record By Hoisting 189,240 Tons in Month of October

THE old Zeigler No. 1 mine of the Bell & Zoller Coal Co., in Franklin County, Illinois has won its place in the sun. In October of this year it produced 189,240 tons of coal. This is the greatest monthly output of coal ever hoisted from a single shaft in the history of coal mining. The great hoist constituted a daily average of 7,008 tons, or approximately 280 railroad carloads, which is a volume of coal sufficient to stagger the imagination at any time, but especially so during a period which is "low" in the coal industry. The fact that it was done is a tribute not only to the engineering and operating staff of the company but also to the sales organization, which is coming to be recognized as one of the most effective in the Midwest.

It is worthy of note that this mine made its great run without any considerable increase being made in either the number of men or in the equipment since the month of March, 1922, when it engaged in a tremendous production race with a nearby mine just before the beginning of the strike of that year. In that month Zeigler established the then world's record for monthly output by hoisting 164,085 tons, averaging 6,077 tons daily. The greatest single day's hoist that month was 7,586 tons. During the past summer the mine was down for about three months while some equipment such as boilers was replaced. However, the mine was not rehabilitated and began producing again this fall without any great increase in mechanical capacity. The company claims that the increased output was gained largely by better organization and higher efficiency.

This historic mine, which is one of the oldest in Illinois, has weathered many a gale, especially during its early years beginning in 1904 when, under the ownership and determined management of Joseph Leiter, it produced its first coal—4,240 tons. Anti-union policies of Mr. Leiter led to various rows with organized labor during which much underground trouble was experienced, ending in an explosion—the last of a series—which wrecked the mine and shut it down in 1908. In December, 1910, it was

reopened, this time under the management of Bell & Zoller, the present operators. Since then its production has mounted steadily as is shown in the accompanying table of production by years.

Up to Nov. 1 of this year the production of No. 1 mine totaled 812,312 tons as compared with 880,428 tons at the same date in 1923. But in 1923 the mine was not shut down during the summer as was the case this year.

The company operates another whale of a mine nearby—Zeigler No. 2—which had produced 1,175,215 tons of coal up to Oct. 31, and was going strong. It has hoisted as much as 6,983 tons in one day and 153,944 tons in one month. Its grand total production since it started late in 1919 is 2,567,131 tons. Thus

### HERE'S A CHALLENGE

HAS ANY MINE in the world, with a single hoisting outlet raised as much coal in its whole history as Zeigler No. 1 has raised since it produced its first coal in 1904? Zeigler No. 1's total for the whole life of the mine up to Oct. 31, 1924 was 12,632,615 tons. Thousands of mines in the world are older—some by 100 years or more—but has any mine made such a contribution to the fuel supply of the world? Bring on your grand totals.

153,944 tons in one month. Its grand total production since it started late in 1919 is 2,567,131 tons. Thus

Annual Production of Zeigler Mine, Zeigler, Ill.

	Tons		Tons
1904.....	4,240	1915.....	816,929
1905.....	103,223	1916.....	965,187
1906.....	234,654	1917.....	937,503
1907.....	321,285	1918.....	925,002
1908.....	522,722	1919.....	1,043,956
1909.....	Closed	1920.....	959,358
1910.....	14,507	1921.....	1,155,278
1911.....	317,827	1922.....	770,716
1912.....	515,270	1923.....	1,023,009
1913.....	555,859	1924.....	812,312
1914.....	633,778		
			12,632,615

it is evident this company, from these two mines alone is capable of producing about 15,000 tons a day and about 340,000 tons of coal per month.

Illinois in its effort to reduce cost and promote efficiency is developing large and ever larger mines, the thickness of the coal, the levelness of the seam and the fact that the measures are seldom eroded and in most cases unfaulted, has made it possible with care in planning to bring large tonnages to the shaft bottom. But with all these favorable conditions we must not overlook the major consideration, the large viewpoint of the operator and the skill of the engineers. Both owners and managers have taken full advantage of the favoring conditions.

# Be Alert to Danger When Unwatering Coal Mines

Use Closed Lights or at Least Have Someone Examine Workings Thoroughly with Safety Lamp Before Men Are Put to Work Removing Water from Flooded Areas

BY L. D. TRACY

Superintendent, Central District Experiment Station,  
Urbana, Ill.

IN THE course of their investigations into the various causes of coal-mine disasters the U. S. Bureau of Mines' engineers have noted that several gas explosions had occurred during the unwatering of mines or shortly after the removal of the water. The coincidence was so marked as to suggest that an extra hazard was present, whenever water, which has been standing against the face of the coal for some time, is suddenly removed whether by natural drainage or by mechanical means.

A typical illustration of this hazard is shown in a gas explosion which occurred in a mine in central Pennsylvania. For main entries, 50 ft. apart with an average grade of 6 per cent, had been driven down the dip of the coal, and from these mains 7 pairs of entries, at intervals of 800 ft., had been turned at such an angle that their grade was slightly rising. From these latter pairs of entries, rooms were turned practically at right angles.

The main entries had been driven for 4,500 ft. and at the face the cover was 400 ft. thick. As far as could be observed, the roof was of sandstone and the floor of clay.

The coal bed being mined was the Lower Kittanning, which has a thickness of about 4 ft. A typical analysis of the coal in that section is: Moisture, 1.6 per cent; volatile matter, 27.0 per cent; fixed carbon, 61.0 per cent; ash, 10.4 per cent, and sulphur 3.8 per cent.

For various reasons the lower part of the mine had been idle for a long time, and consequently had filled with water.

## BROKE STOPPINGS AND DELAYED THEIR REPAIR

When it was decided to unwater this part of the mine, pumps were installed in the main entry, and at the time of the explosion the water was being lowered rapidly. Large holes had been broken in the brick stoppings between the main entry, which was being used as an intake for the fresh air, and the return aircourse, consequently the ventilation in that part of the mine was very poor.

During the work of unwatering this section of the mine, the mine superintendent, the fireboss and three other men went down the slope to a cross entry near the level of the water to make temporary repairs at the holes in the brick stoppings. The two officials carried flame safety lamps, but the other men wore carbide lamps.

From the evidence obtained during the investigation

of the disaster, it would appear that the two officials walked a short distance up the side entry and set in motion a slight air current, which caused the accumulated gas to work its way slowly to the spot where the men were working on the brick stoppings. As these men had open lights, the gas was ignited and flashed up the side entry, where the superintendent and the fireboss were standing, and burned them fatally.

Analyses of the mine air after the explosion showed 1.35 per cent of methane in this section, which had little if any ventilating current. As the mine was worked on an open-light basis, it must have been considered to be a non-gaseous mine.

A similar explosion in which eight men eventually lost their lives occurred in what is known as the Thick Freeport bed in western Pennsylvania. This bed is now thought to be a peculiar thickening of the Upper Freeport bed, and at this particular mine it was about 9½ ft. thick, including a slate and bony coal band of about 8 in. The roof was a good qual-

ity of shale, and but few roof falls were in evidence. A typical analysis of this coal, excluding the band near the center, would be as follows: Moisture, 2.09 per cent; volatile matter, 37.09 per cent; fixed carbon, 54.12 per cent; ash, 6.70 per cent; sulphur, 2.92 per cent. The average thickness of cover was about 120 ft. The mine was a small one, covering approximately 1½ acres, and had been abandoned ten years earlier.

## ANOTHER CASE IN WHICH GUN WASN'T LOADED

The mine had only one shaft, 50 ft. deep, which was divided by a board partition into two parts, one for hoisting and one for ventilation. Prior to the explosion, natural ventilation was employed, although a fan had been installed. The mine had not been worked on any particular system, rooms and entries being driven in a more or less haphazard fashion. It is understood that the mine had been considered, when previously operated, to be non-gaseous, and open lights had been used.

During the period of idleness there had been an accumulation of water in the mine, which could be removed only at the expenditure of much energy. A centrifugal pump of a capacity of 500 gal. per minute, driven by a 250-volt direct-current motor, had been installed. A few days prior to the explosion, the unwatering of the mine had been completed to such an extent that surveyors could enter and begin a survey of the mine workings.

During the progress of the survey the men experienced trouble in keeping a light in the flame safety lamps which they were using. It so happened that none of the men had been trained in the use of a safety lamp in detecting the presence of explosive gas, and did not realize the reason why their lights were extinguished, and so exchanged them for electric flashlights, with which they finished the survey.

During the work of unwatering, the only lights supposed to have been used by the workmen were ordinary incandescent lamps, a special feed wire being taken down the shaft to supply the light required by the men working around the pump. On the day of the explosion, five men were engaged in moving the pump from a point near the shaft to a place closer to the sump, a distance of 60 ft., and the other three men were placing buntons and guides in the shaft.

While thus engaged, there was a sudden explosion which completely wrecked the hoisting equipment, and blew the three men, who were working 40 ft. below the collar of the shaft, to the surface, and landed them 30 or 40 ft. away from the shaft. Two men in the mine were instantly killed, and three men who were taken out alive, died later from burns and the effect of the afterdamp.

From evidence obtained during the investigation conducted later, it was concluded that one of the men in the mine must have ignited the gas by striking a match. Analysis of air samples obtained in the mine after the explosion showed 0.54 per cent methane.

#### MINE FAN WAS STOPPED AND GAS GATHERED

An explosion in a West Virginia mine which killed one man, and which would have resulted fatally for two others but for a rescue party, was closely associated with the presence of an accumulation of water.

This mine was working the Pittsburgh bed which at this point is 6½ ft. thick. A typical analysis of the coal in this mine is as follows: Moisture, 2.8 per cent; volatile matter, 37.0 per cent; fixed carbon, 51.6 per cent; ash, 8.6 per cent; sulphur, 2.5 per cent. The mine was opened by a slope, and when running produced 150 tons of coal per day.

The mine had been idle for about a week, and owing to floods in that section of the state a much larger volume of water had collected than usual. Three men, including the mine superintendent, entered the mine to make arrangements for pumping out the water that had collected. There was no ventilation as the fan had been shut down. While moving around, a body of gas was brought in contact with an open light and caused the fatal explosion.

One of the most clean-cut cases illustrating the point in question was an explosion which occurred in the opening of a new mine in Clearfield County, Pennsylvania, in which three men were killed.

The coal being mined was 4 ft. thick, and had 35 ft. of slate roof on top of which was a bed of sandstone. The coal bed is supposed to be the Lower Kittanning, although there is some doubt of its identity. The main entrance to the mine was a slope about 500 ft. long, having an average grade of 25 per cent.

Approximately 160 ft. west of the mouth of the slope a shaft 150 ft. deep had been sunk to the coal. From the foot of the shaft two entries had been driven for a distance of about 300 ft., and then stopped on account of water.

Just beyond the foot of the slope two entries had

been turned at right angles and driven parallel to and in the same direction as a line from the mouth of the slope to the center of the shaft. From these two cross entries, two entries were turned and driven to meet those which had been started from the shaft bottom.

About two weeks prior to the accident, one of these latter entries had been undercut into the corresponding entry driven from the shaft. The parallel at the same date had about 15 or 20 ft. to go before it met its corresponding shaft entry. Prior to the cutting through of the first mentioned entries, the water was said to have continued to back up until it stood 60 ft. deep in the shaft.

The ventilation of the entire mine was weak, probably not 3,000 cu.ft. of air going through all the workings. Open carbide lights were used by the men, and no flame safety lamps were at the mine before the explosion. The statement was made that no gas had ever been detected, although this fact has been questioned.

#### COAL UNDERCUT RELEASED GAS INTO ENTRY

On the night of the explosion, three men were working in the entry which had been cut through into the corresponding entry advancing toward it from the shaft, and which for some time previous had been filled with water. At this particular time, however, the water had been drained through the undercut which had been made, until there was a space of about 18 in. between the surface of the water and the roof.

The evidence seemed to show that part of the coal had been shot down, releasing the gas that had collected in that part of the entry which had been full of water. As the men moved around, this gas was ignited by their open lights and caused the death of the three. That the gas was not present when the men first went in was indicated by the fact that the coal had been shot down; if the gas had been present before the coal was shot, it would have been ignited while the men were preparing the shot.

Flooding a mine to extinguish a fire is another phase of this potential hazard. There is one case on record where the workings were flooded, and the water backed up into the shaft for 60 ft. or so. Evidently gas accumulated under considerable pressure, as several times it puffed out of the shaft, blowing the seal off the top. In this case there was no explosion of the gas so released, but if an open light had been near, there would have been at least an ignition.

#### ENTER DRAINED AREA WITH PRECAUTION

It is true that the cases cited are not sufficient to justify the hard and fast statement that there is always an accumulation of gas whenever water backs up under a head into mine workings. However, there is sufficient justification for issuing a warning that extreme care should be exercised when entering an area from which any considerable quantity of water has been drained, and especially so if that water has been standing under a high head.

It would be on the side of safety to use only approved closed lights when working around such an area; or in case open lights are used, no one should be allowed to begin work until a thorough examination has been made by a person experienced in detecting explosive gas by means of a flame safety lamp. The safest procedure is to carry both flame safety lamps and electric cap lamps.

## Adapting Shortwall Machine To Center Cutting

Undercutter Can Be Mounted on Truck So as to Cut a Kerf from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  Ft. or from 3 to 4 Ft. Above Track

**I**N MANY mines the face can be better prepared for shooting by center cutting rather than by under-cutting. This is particularly true in coal beds that carry a parting that may be removed by a center cut. Heretofore, most cutting of this kind has been possible only by the use of a specially designed and comparatively heavy machine. Recently the Sullivan Machinery Co. of Chicago, has developed a truck for an ordinary shortwall undercutter which enables this machine to perform practically the same work as a center cutter.

This machine consists of a standard Ironclad room-and-pillar machine, driven by either direct or alternating current, mounted on a special truck so arranged as to permit the cutting out of a parting without the machines leaving the truck. With this cutter, workings

Rear View Showing Swinging Device

The cutterbar is revolved through its working arc by means of an idler pulley engaging the feed chain, a clutch and a pinion that meshes with a rack or quadrant. The machine is sumped and the truck propelled in the usual manner.

22 ft. wide may be driven successfully, while the circular kerf may be carried to a depth of 8 ft., the ribs or side walls meanwhile being carried straight.

A somewhat similar machine, but one without adjustment for height, has been used successfully for a number of years in West Virginia. It has been employed chiefly in driving entries and in narrow work in general, or in other words, in places where the track may be carried up to the working face.

The lowest setting of the swivel plate gives a minimum height for the bottom of the kerf of 19 in. By extending a set of jackscrews the height of the bottom of the cut may be increased from this figure up to 31 in. On the other hand, the machine may be so built at the factory as to place the maximum height of the kerf at 48 in. above the rails and permit a downward adjustment to a minimum height of 36 in., both measurements being taken to the bottom edge of the incision.

The machine is rotated on its turntable by passing the feed chain around an idler sheave on the rear of

General View of Machine

The cutter itself is a standard machine, but the truck necessarily is of special design. The two details of greatest importance in this truck are the swiveling device whereby the cutterbar is made to describe an arc and the jackscrews by means of which a variation in the height of kerf may be effected.

the housing. A suitable clutch mounted above this idler permits the motion imparted to it to operate a set of gears meshing with a rack on the truck body, thus swinging the cutterbar through a circular arc. The necessary advance for sumping is accomplished by anchoring the feed chain at the face, and thus moving the truck along the track up to its work.

Machine propulsion and the arrangement of the cable reel coincide with the propulsion and reel of the Tip-turn truck used with the standard machine. A friction drive and brake are supplied by means of which a maximum speed of four miles per hour along the rails may be attained. On the other hand, this speed may be reduced to a few inches per minute, thus permitting the machine to enter rooms, round curves or cross switches without danger of derailment. The brake is sufficiently powerful to hold the machine on any ordinary grade. A reel of the self-winding type, capable of picking up the cable when the machine is at rest, as well as when in motion, is supplied. This reel is fitted with the usual roller guides to spool the cable evenly.

This outfit, as may be noted from the accompanying illustrations, forms an extremely serviceable unit for the removal of bands or partings occurring in a coal bed. The truck itself weighs about 4,500 lb., and the machine, with  $7\frac{1}{2}$  ft. cutterbar, weighs approximately 5,000 lb. Thus the combination of the two, or the complete center-band cutter, weighs less than five tons when ready for operation.

A Safety Provision Adopted in Alabama Mines

A safety walkway is provided in all underground passages that are carried forward full width. This walkway lies between the room track on one side and the packwall or gob on the other. It furnishes a straight, free passage for the workmen in traveling up or down the room.

## News Of the Industry

### South Penn Collieries Co. Emerges from Sproul Hard-Coal Merger

Scranton, Pa., Nov. 18—The much discussed merger of independent anthracite companies in process of negotiation by a group of men led by former Governor William C. Sproul was consummated during the past week, when the Legitts Creek Anthracite Co. and the Von Storch Collieries Co. with several other properties, in all six groups, were consolidated. The newly merged company is known as the South Penn Collieries Co.

The new company owns mineral rights underlying 3,320 acres of anthracite lands in Lackawanna, Northumberland and Schuylkill counties and holds leaseholds of additional mineral rights underlying 620 acres. It represents the consolidation of the following properties, owned or controlled through leaseholds by previously existing companies; The Von Storch, Legitts Creek, Shepton, Treverton, Randolph and Silverton.

#### One Property Still Undeveloped

Of the six groups of properties, five are developed with mining operations and collieries and one is to be developed. The oldest property, which was first worked in 1859, has an operating history extending back over a period of more than 65 years. The company also will own or control four washery operations. Recoverable coal underlying the properties in which mineral rights are owned has been estimated at more than 26,000,000 tons; recoverable coal underlying the properties in which leaseholds of mineral rights are held is estimated at 11,000,000 tons. In the properties already developed there are five collieries with two shaft openings; three slope openings and nine drift openings, with present equipment for annual production in excess of 1,600,000 tons.

The Von Storch and Legitts Creek properties are situated in the Wyoming field, in the Scranton district of Lackawanna County. The mines open into one another. The workable coal, in veins 3 ft. or more in thickness, underlying these properties is in twelve and ten veins respectively, the veins varying from 3 ft. to 10 ft. in thickness.

The Shepton property is situated on Green Mountain, in Schuylkill County, in the eastern part of the central field, about 10 miles west of Hazleton. In this property there is in No. 1 Basin one vein 17 ft. to 13 ft. thick; in basin No. 2 one vein 8 ft. thick; No. 3 basin is believed to contain one or more veins not yet proved. It adjoins the Oneida No. 1, 2 and 3 collieries of the Lehigh

Valley Coal Co. and the Girard estate.

The Treverton property, where the Katherine mine and colliery is owned and operated, is in Northumberland County, in the western part of the Schuylkill anthracite field, about 10 miles southwest of Shamokin. The workable coal underlying the Treverton property, of or exceeding 3 ft. thick, is in five veins, varying from 3 to 10½ ft. thick.

The Randolph and Silverton properties, which are to be operated under leaseholds, are in Schuylkill County, in the southern part of the anthracite field, the former just west of Port Carbon and the latter about 4½ miles west of Pottsville. The coals underlying these properties are of good quality, the workable coal underlying the Randolph property being in eight veins from 3 to 10 ft. thick, and that underlying the Silverton property in fifteen veins, of which five from 4½ to 10½ ft. thick have been developed.

Officers of the South Penn Collieries Co. will include William C. Sproul, president; Newton P. Jackson, treasurer; Alexander Staples, secretary; Warren T. Acker, manager of the Lackawanna district; Hubert D. Johnson, manager of the Schuylkill district. Directors of the company include Governor Sproul, B. Dawson Coleman, president of the Ebensburg Coal Co., and director Baldwin Locomotive Works; Alfred A. Corey, Jr., president Vanadium Corporation of America; Francis V. du Pont; John H. Mason, chairman of the Bank of North America, and John P. Crozer, president of the Crozer Land Co. and director of the Crozer-Pocahontas Coal Co.

### Western Kentucky Strike Runs Steadily Onward

The end of the week of Nov. 10 found the strike in western Kentucky going into its seventh official month, although some mines were closed down two weeks or more prior to April 15. Much suffering is reported in the Central City district, where miners are having trouble in getting even medicines for their sick. Many miners admit that they are willing to return to work, but are afraid to do so. Unless an agreement is reached soon it looks as if the field may be down until the autumn of 1925, as the active season will soon be over unless there is an adjustment. A few mines around the edge of the district are working on 1917 wages.

### Soft-Coal Industry Benefits Consumers, Says Coolidge

In an address at a meeting of the U. S. Chamber of Commerce, President Coolidge indicated that he favored further reduction in federal taxes, pointing out that fuel and other articles pay a tax to the government and that the people pay these taxes when they buy such necessities.

The President stressed the fact that the bituminous-coal industry benefits consumers. He said: "When we look for an example of benefiting consumers we shall find it in the bituminous-coal industry. Three years ago there were about 9,000 mines, or 30 per cent more mines and miners than could be given regular employment. The Department of Commerce found there was need of more cars, more summer storage and more industrial peace. These have been accomplished, with the result that while in the profiteering period of 1920 run-of-mine coal averaged \$5.64 a ton, notwithstanding the strike in 1922 it then averaged \$3.67 per ton, and for the year ending June 30 last it averaged \$2.23 per ton. This industry has been organized but not monopolized; it has between 7,000 and 8,000 competing mines, and no person or group controls more than 2 per cent or 3 per cent of the production."

### Lewis and Aides Almost Sure To Be Re-elected

Present officers of the United Mine Workers will have a candidate appearing against each of them on the ballot in the annual election of Dec. 9, but the strength of the opposition is regarded as slight, and the present incumbents probably will be elected by substantial majorities. The ballot for the election showing the names of the candidates was made public recently. John L. Lewis, international president, is opposed by George Voyzey, of Verona, Ill.; Philip Murray, international vice-president, is opposed by Arley Staples, of Christopher, Ill., and William Green, secretary-treasurer, is opposed by Joseph Nearing, of Nova Scotia.

All of the members of the auditing and credential committee, the board of tellers, and the delegates to the American Federation of Labor are up for re-election and also have opposition.

## Joint Safety Conference Studies Rock Dusting

A joint safety conference held in the auditorium of the Chamber of Commerce, Pittsburgh, Pa., Nov. 10, was participated in by the American Society of Safety Engineers, the engineering and mining sections of the National Safety Council, the Pennsylvania Department of Labor and Industry, the Coal Mining Institute of America, the U. S. Bureau of Mines, the Pennsylvania State Department of Mines and the Western Pennsylvania Safety Council.

Richard H. Landsburgh secretary of the Pennsylvania Department of Labor and Industry, presented at the morning session a program of co-operative effort in safety work of industries in Pennsylvania with the Department of Labor and Industry. J. T. Ryan, of the Mine Safety Appliances Co., presided at a symposium on "Rock Dusting for the Prevention of Mine Explosions." Edward Steidle, Carnegie Institute of Technology, spoke on "The Need of Rock Dusting," and T. G. Fear, Inland Collieries Co., on "Rock Dusting the Indiana Mine."

At the afternoon session J. A. Oartel, Carnegie Steel Co., Pittsburgh, was general chairman. He introduced the Rev. C. H. Rust, Wilkesburg, Pa., whose subject was "Men and Machines." His talk was followed by a symposium on "Practical Safety Kinks," with exhibits and slides, contributors to which were C. B. Auel, Westinghouse Electric & Mfg. Co.; J. A. Northwood, Bethlehem Steel Co., Johnstown, Pa.; A. R. Pollock, Ford Collieries Co.; J. T. Ryan, Mine Safety Appliances Co.; A. C. Gibson, Spang Chalfant & Co.; H. F. Webb, West Penn system, and C. F. Abel U. S. Aluminum Co.

A symposium on "Shop Safety Education Stunts," with exhibits and slides, had as participants A. C. Cook, Carnegie Steel Co., Youngstown, whose subject was "Running a Safety Drive," and E. S. Wright, Edgar Thomson Works Carnegie Steel Co., Braddock, Pa., who spoke on "Four Years Without a Lost-Time Accident."

## Merger Plan Breaks Down Once More

For months a "big deal" has been talked of in western Kentucky. It was to result in a combine of seven big mines of about six companies. But somehow financial arrangements were not made. Now it has been postponed again, an option having expired on Nov. 10. L. H. McHenry, Louisville bond broker, is said to represent the buyers. Properties of the W. G. Duncan Coal Co., Pacific Coal Co., Wickliffe Coal Co., Greenville Coal Co. and Nelson Creek Coal Co. were among those included in the proposed deal. All of these mines are strike bound at the present time. Banks are slow to finance striking properties and, strangely, the present owners want a real return from anyone who talks of buying. Hence nothing happens.

## Low Prices Realized in Disposal of Holdings of Jewett-Bigelow-Brooks

The tangled affairs of the defunct Jewett, Bigelow & Brooks Coal Co. finally have been straightened to the extent of disposing of nearly all of the eastern Kentucky coal properties once operated by the company. Creditors suffered heavily because the various public sales of mines practically fell flat. It is freely said that the returns will hardly more than pay the salaries and expenses of the receivers, E. L. Douglass and John L. Richey, of Cincinnati, Ohio.

The best mine in the group, the First Creek Mining Co. property in the Hazard field, sold to R. S. Young, of Knoxville, said to be acting for the Blue Diamond Coal Co., of Cincinnati, for \$100,000, as reported last week in these columns. This mine will be operated as the Sapphire Coal Co. The Hazard Jellico Coal Co. was returned to the Harvey Coal Co., of Knoxville, Tenn., the lessor. The third Hazard property, the Black Joe Coal Co., sold at auction for \$26,500 to W. E. Davis, of the Midland Mining Co.

In the Elkhorn district the J. B. Elkhorn Coal Co. mine sold for \$40,000 to Captain R. R. Smith, of Huntington, W. Va. These openings are on Shelby Creek. The Harlan Fox Coal Co., which was the only Harlan property of Jewett, Bigelow & Brooks, brought \$25,110 from C. Paul Downard and Elmore H. Manning, Louisville (Ky.) jobbers, who are forming a new company to operate under the old name of the mine.

In Bell County, the J. B. Straight Creek Mining Co., on which an original bid of \$7,000 had been made, finally was sold for \$15,000 to R. L. Moss, of Pineville, Ky. Two mines of the Roth Coal Co. on the Cumberland Ry. near Artemus, Ky., were in the J.B.B. string. No. 1 was returned to the lessor, Ray Moss, of Pineville, Ky. No. 2 mine, which is involved in further litigation and whose railroad connection is broken by the collapse of a big trestle, was sold for \$5.

Three properties remain in the hands of the receivers. They are the Jaybee Jellico Coal Co., with a mine that has been operating in the Dean seam at the edge of Pineville, and two West Virginia mines—those of the Seminole Gas Coal Co., close to Clarksburg, and of the Guyan Mining Co., at Logan.

All of the sales were approved by the federal court in Covington, Ky.

Explosives manufactured in 1923 exceeded by 26.8 per cent the output of 1921, figures just made public by the Bureau of the Census show. The number of men employed in the industry increased 42.7 per cent. The amount paid for wages was 37.8 per cent greater and the cost of raw materials was 28.9 per cent greater. One of the striking features of the Census return was the increase of 82.9 per cent in the output of permissible explosives. In 1923 the total output was 67,334,759 lb. There was a large increase in the output of dynamite, which in 1923 amounted to 262,290,012 lb., an increase of 56.8 per cent over 1921.

## Ford Scheme Has Dock Men on Ragged Edge

Ford is playing havoc around the Head-of-the-Lakes. This is not so much from what he is doing at present, as he has little coal to sell, but because the dock men are unable to tell where the lightning will strike next year. The trade has been circularized and is urged to buy coal (Kentucky) at 20c. above dock price in carload lots. This cuts out the dealer, or would in other lines of coal. The Ford agents are handling the coal but are not enthusiastic, as they have to guarantee payments and make collections, all for 25c. a ton. The advertising states that other coals carry 13 to 31 per cent ash and that Ford Kentucky is far superior to this. This point, of course, is debatable, as the other dock men claim a much lower percentage of ash than stated by Ford.

## Name Committee to Effect Uniform Tax Rulings

In accordance with a resolution adopted at the Sacramento convention the following members of the general tax committee of the American Mining Congress have been assigned by the tax division as a sub-committee to effect uniformity and justice in income taxes on coal operators: R. V. Norris, Wilkes-Barre, Pa.; Howard N. Eavenson, Pittsburgh; George Wolfe, Beckley, W. Va.; T. T. Brewster St. Louis, newly appointed on the committee; J. G. Puterbaugh, McAlester, Okla., and Paul Armitage, New York.

The tax division has asked the Internal Revenue Commissioner to reverse the decision of the revenue solicitor which gave an adverse interpretation to Art. 222 relating to items which should be charged to expenses. Mr. Brewster, chairman of this sub-committee, and McKinley W. Krieger, chief of the A.M.C. tax division, conferred with J. G. Bright, Deputy Commissioner of Internal Revenue, on administrative matters pertaining to the audit of income tax returns of coal companies. Mr. Bright outlined several recent changes in office procedure to obtain maximum efficiency, and stated that the entire field force of the income tax unit has been instructed to co-operate with taxpayers in every possible way to effect prompt and proper adjustments of tax liability. It was agreed that the American Mining Congress sub-committee should devote special attention to proposals that will clarify the regulations and simplify the work of the unit, as well as the taxpayers.

The sub-committee it was announced, will proceed at once with the consideration of certain problems outlined by John Laing, Charleston, W. Va., author of the resolution creating this committee, including the recent adverse interpretation by the Solicitor of Internal Revenue of Art. 222, Regs. 45 and 62, which ruling the American Mining Congress has sought to have revoked.

## Central Pennsylvania's Long Slump Breaks as Mines Show Signs of Life

That the coal industry is picking up in northern Cambria, Clearfield and Centre Counties is revealed by a recent survey of conditions in central Pennsylvania. Osceola Mills, in the Clearfield region, shows unmistakable signs of activity. Penn mine No. 5 is working, Dushannon mine is doing four days a week and No. 10 is working four days a week and other operations are doing equally as well. This town has the Pennsylvania R.R. yards on the mountain and with the shipping of coal the yards are active and business is looking up along all lines. A further increase in production is confidently expected with the advent of cold weather.

Houtzdale, another important coal-mining town in the Clearfield region, shows signs of revival. During the World War and for a few years thereafter, mines were opened in the back yards of homes and coal was conveyed from them in wheelbarrows, wagons and trucks to railroad sidings and loaded on cars. This prosperity could not last and soon Houtzdale found itself with a lot of mines and a lot of miners on hand and no market.

### Plan for Permanency

Houtzdale survived the dark days, however, and hope has revived. The most promising sign is that the operators are planning for permanency rather than for booms. More than a year ago the Hale Coal Co. awarded a contract for sinking a shaft to tap the lower vein of high-grade coal at Morann, near Houtzdale. That operation has been completed. The shaft is of concrete, 180 ft. deep, and is electrically operated. It has four compartments, two of them for hoisting coal exclusively, the cages being self-dumping. Designed for a capacity of 250 tons per hour, the mine is equipped to ship run-of-mine, lump or slack sizes. William Wetter, of the Madeira-Hill Coal Mining Co. is general manager of the Hale company and other Madeira-Hill officials are connected with the new company.

At Mountindale, in the northern part of Cambria County, where the principal industries are coal mining and brick making, one largely dependent on the other, the Harbison-Walker Co. is now working, giving employment to 275 men in the coal mine, in the clay pits and on brick work.

Dependent upon the coal industry, Philipsburg, one of the oldest coal towns in central Pennsylvania, has felt keenly the severe slump in that industry. Not only did the operator and the miner suffer, but all other business. A profound spirit of pessimism prevailed. As a result, many men left the region for other locations and to seek other employment where industry was more stable.

A new spirit has appeared of late, however, with the resumption of operation at the mines. At Winburne, the Pennsylvania Coal & Coke Co. and Peale, Peacock & Kerr are working four days a week.

At Morrisdale, the Cunard Coal Co.

John Laing

President of the Wyatt Coal Co., Charleston, W. Va., who was elected president of the Kanawha Operators' Association at the annual meeting, held recently in Charleston. The other officers chosen were: D. H. Morton, vice-president; John L. Dickinson, treasurer, and D. C. Kennedy, secretary. The new board of directors consists of Col. W. M. Wiley, Col. E. O. Dana, H. L. Warner, F. A. Harris, W. C. Mitchell, F. H. Morton and C. A. Cabell.

and the Morrisdale Coal Co. are operating on half time with better prospects for the future. The Harbison-Walker Refractories Co. is operating its plants at Philipsburg, Blue Ball and Wallace. Brick plants at Sandy Ridge and at Retort also are running, with the prospects improving weekly. These plants all consume considerable coal and when the one is in operation the other must go. Improvement in all other towns of the region is noticeable and depression has given a place to optimism. With the election over, winter coming on and other industry starting up, prospects for the coal industry of the region are better.

## Pittsburgh Terminal Absorbs Meadowlands Company

The Pittsburgh Terminal Coal Co. and the Meadowlands Coal Co. are to be merged into a new corporation known as the Pittsburgh Terminal Coal Corporation, according to an announcement made early last week. The new company will have a capitalization of \$4,000,000 of 6 per cent cumulative preferred stock and \$12,000,000 of common stock.

The present owners of the Pittsburgh Terminal Coal stock will receive all the preferred and \$8,000,000 of common stock of the new company. Holders of the Meadowlands Coal stock will receive \$4,000,000 of the new common stock. The new company will have 20,000 acres of coal land with an annual output of approximately 15,000,000 tons of coal.

The Pittsburgh Terminal Coal Co. is a subsidiary of the Pittsburgh & West Virginia Ry. but under a plan now before the stockholders the coal property is to be segregated from the railway property.

## Production of Coal in Canada During August Was Lowest of the Year

Coal production by Canadian mines during August, according to a report by the Dominion Bureau of Statistics, was the lowest of the year. The decrease in quantity from the previous month was 7 per cent, falling from 730,316 tons in July to 682,878 tons in August. Compared with average output during the past five years the decrease was 45 per cent. These decreases may be explained by the strike in Alberta and British Columbia (District 18). The monthly average production of Alberta and British Columbia for the five preceding years was 686,485 tons as against 254,519 tons during August of this year. In Nova Scotia production fell from a monthly average of 504,014 tons to 403,739 tons, a decrease of 20 per cent.

Imports of coal from the United States and Great Britain decreased about 6 per cent. August imports amounted to 1,557,141 tons while in July 1,655,712 tons was brought in. The August importations this year were 21 per cent lower than the five-year average for the month. During the month 50,641 tons was imported from Great Britain. Total importation of all coal for the eight months of 1924 was 10,577,823 tons, or only 6 per cent below the preceding 5 year average for the period.

Imports of anthracite for August totaled 329,377 tons, which is 20.7 per cent less than in July but 22 per cent less than the five-year average for the month. Anthracite imported from the United States amounted to 286,964 tons, while 42,413 tons came from Great Britain. The anthracite imports during the 8 months of 1924 were 2,641,275 tons, a decrease of 9 per cent from the five-year average for this period.

Exports of Canadian coal during August were 10 per cent lower than in July. The quantities were: August, 63,415 tons, and July, 70,235 tons. Comparison of August exports with the preceding five-year average shows a decrease of about 71 per cent.

Figures on output, imports and exports, as outlined above, show that the quantity of coal made available for consumption decreased about 7 per cent from the previous month, the August total being 2,176,704 tons as against 2,315,793 tons during July. In comparison with the five-year average for the month, the August available tonnage was lower by 27 per cent. The total coal available for use in the first eight months of 1924 amounted to 18,322,277 tons.

The total number of men employed in the coal mines of Canada during August was 19,280, of whom 14,682 worked underground and 4,598 on the surface, as compared with a total of 17,522 in July, of whom 13,392 worked underground and 4,130 on the surface. The monthly production per man was 35.4 tons for August as against 38.1 tons per man for July. During August the production per man-day was 1.9 tons as compared with 2 tons in July. The tonnage lost was largely due to lack of orders in August.

# Jacksonville Agreement Proves Setback To Union Fields

Fall in Prices Restricts Profits to Lowest Cost Producers—Hundreds of Mines Forced to Close—Autumn Revival Benefits Mostly Non-Union Operations

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

After seven months of its operation it is possible to draw certain concrete conclusions as to the effect of the Jacksonville agreement. While it is yet too early in the life of that compact between the United Mine Workers and the operators of union mines to judge the ultimate effect on the patient of the "self-imposed surgical operation" advised by Dr. Hoover, something can be said as to the present state of health of that patient. All admit that prices have fallen to levels which restrict profits to the lowest cost producers. Hundreds, if not thousands, of mines have been forced to close. Most of the operators who have closed down their properties hope to reopen them, but sooner or later they must realize that that day never may come.

## Many Large Mines Idle

Of the mines reporting to the U. S. Geological Survey, which are the larger commercial operations and not wagon mines, some 35 per cent are closed entirely. The remainder, with few exceptions, are working only part time. The story is told by the accompanying table. These figures are abstracted from the weekly reports of the Geological Survey. The table compares conditions in the union fields with those in the non-union fields. It uses as a standard of comparison the percentage of full time at which the mines in each district are operating. The first column shows this percentage for the week of July 26, four months after the Jacksonville agreement went into effect. The second column shows the percentage for the week of Oct. 25, practically concluding seven months' experience under the compact. The table follows:

Percentage of Full Time Worked at  
Union and Non-Union Mines

District	UNION	
	July 26, 1924	Oct. 5, 1924
Illinois.....	28.6	45.9
Indiana.....	24.2	38.5
Southern Ohio.....	12.7	
Eastern Ohio.....	64.0	62.5
Pittsburgh (rail).....	35.3	51.6
Central Pennsylvania.....	39.2	55.6
Fairmont.....	32.0	43.6
Western Kentucky.....	23.1	37.4
NON-UNION		
Westmoreland.....	44.2	63.2
Winding Gulf.....	47.6	65.1
New River.....	44.8	64.1
Pocahontas.....	53.8	76.9
Tug River.....	56.3	82.6
Kanawha (C. & O.).....	43.7	56.8
Logan.....	70.1	75.7
Kenova Thacker.....	46.0	62.6
Northeastern Kentucky.....	58.2	61.3
Hazard.....	50.9	66.8
Harlan.....	48.1	67.5
Virginia.....	66.9	75.0

It will be noted that the comparison is against the union fields in almost every case. Taking the condition after

four months of the agreement it will be noted that out of the eight union districts there is only one that reached 40 per cent of full-time operation. The single exception is eastern Ohio, which has specially favorable lake connections. On the other hand, of the non-union districts there is not one that did not operate at more than 40 per cent of full time. Even the Kanawha operators on the Chesapeake & Ohio R.R. made a showing of 43.7 per cent. Though running open shop they are less free to reduce wages and labor costs than are the operators in the non-union strongholds. Thus it was that the competing Logan district, just over the mountain, which ships the same kind of coal to the same markets, was able to show a figure of 70.1 per cent.

Of course the first column represents conditions when the depression was at its depth. In July the weekly output was barely seven and one-half million tons—no greater than during the great depression of 1921. It was a time when the market was deadened by heavy stocks and by the state of the principal coal consuming industries.

## Non-Union Output Higher

The figures in the second column, however, are for a period when the output is running above ten million tons—not far from the normal at that season of the year. During the week of Oct. 25 the output was 10,300,000 tons, or 2,800,000 tons greater than the output for the week of July 26. The question is, Who has supplied this additional demand? The figures show that the bulk of it has been supplied by the non-union fields.

The condition after seven months of the Jacksonville agreement is indicated by the fact that of the eight union districts only one was working at 60 per cent of full-time operation. The exception is the same as cited before, eastern Ohio with its geographical advantage with respect to the lake trade. On the other hand, each of the twelve non-union fields, with the exception of Kanawha, was working in excess of 60 per cent of full time. Thus it is apparent that the diversion of business from the union to the non-union fields continued during the more active demand of the autumn, even when the need for coal is increased as the country moves from depression into abundant prosperity.

It is true that operations in the union districts are making a better showing than they were at the trough of the slump last summer. Every one of the union districts except the Ohio fields shows a higher percentage in the last column than it does in the first, but the increases for the most part have been small as compared with those in the non-union fields, some of which—Poca-

## This Mule Had Designs On the "Movies"

"The anecdotes of bright mules which have been appearing in *Coal Age*," says an engineer, "recall an interesting experience I had in 1917 when my company was receiving a considerable portion of the output of a stripping mine in northern West Virginia. I found that snapshots would tell conditions and progress of operation better than a lengthy report; therefore I carried a camera wherever I went. 'Joe' was a mule whose duty it was to spot mine cars. He was said to be about 40 years old but was pretty sleek and looked good for many more years. I took his picture once or twice. After that whenever I had the camera with me he would straighten up, prick up his ears and look at me as if to say 'Don't I look pretty'? If I did not have the camera he would remain in his usual semi-comatose state with eyes half closed, ears drooping and legs appearing about ready to collapse. I believe 'Joe' could tell at 100 yards whether I had the camera or not."

Any more?

hontas, Tug River and Logan—are reporting running time in excess of 75 per cent, which is ahead of all but the best performance during the war.

The foregoing comparison is confined to the fields of the Appalachian and middle Western regions. The remainder of the country is excluded because it is in the regions mentioned that the drama of coal is played. The area of the Central Competitive field and that of its non-union antagonists are those from which the Northwest draws both its lake and rail supplies. These are the areas that furnish the coal for the Canadian and the tidewater trade and for the fueling of the industries of the North and East. What happens outside these areas has little bearing on the making of wage agreements. The fate of the Jacksonville treaty will be settled by the results in the fields listed in the table.

## Average Figures Deceptive

One thing is not revealed by figures of the average time worked. An average may be a deceptive thing, yet none disputes its usefulness. It never shows the extremes which go to make up the average. The averages shown in the table are made up of very unlike items. Into them go mines which are working full time and mines which are shut down entirely. The figures do not show that along with the shifting of business from union to non-union fields is a shift from the little mine to the big mine; a shift from the weak to the strong; a shift from the thin-vein to the low-cost thick-vein mines. These all represent complications which have followed the major operation at Jacksonville; their ultimate effect on the health of the patient still is to be determined.

## Safety Education Planned In Kentucky

J. Wood Vance of Glasgow, Ky., State Representative from Barren County in the 1916, 1917, 1918, 1920 and 1924 General Assemblies, was selected Nov. 10 as referee of the Workmen's Compensation Board to serve in western Kentucky. His position was created due to a 400 to 500 per cent increase in the work of the board, officials said. A special meeting of the board, W. H. Jones, chief of the Department of Mines; representatives of coal operators, employees and compensation insurance carriers of Kentucky resulted in a tentative organization to promote greater safety. Those attending were R. C. Thomas, T. H. Ruddy, E. R. Glayton, R. E. Hume, J. E. Johnson, E. D. Johnson, R. E. Grace, C. J. Neekamp, representing the operators; Calvin Mays, the employees; D. A. Macwhirter, the insurance carriers; Alvis S. Bennett, R. T. Kennard, Joseph E. Lee, A. T. Bryson and Forest J. Fields, the board, and Mr. Jones. Following decision to form a permanent organization, a committee was appointed to draft a definite plan of procedure to carry out the proposed "education program for accident prevention and safety-first practices." The meeting adjourned to meet on Dec. 3 at Lexington.

©Harris &amp; Ewing

### H. Foster Bain

Director of the U. S. Bureau of Mines, who will sail from the United States for Argentina on Nov. 22. Accompanied by three mining experts he will make an extended study of the possibility of developing the iron and steel industry in the South American republic. He goes at the request of the Argentine Government.

coal industry, will be vice-president and general manager.

Engineers familiar with the development and present stage of the Trent process activities believe that it has a promising future in the field of fuels, especially with regard to domestic heating, gas manufacture, gas producers, pulverized combustion, locomotives, steam plants, power and heating.

The distillation of byproducts should give an additional value. Plants are now in operation at Toledo, Ohio; Spokane, Wash.; Lapugny, France, and under construction at Moundsville, W. Va., and near Clearfield, Pa. Contracts have been signed for the erection of other plants.

## 14,000 Strike at Collieries Of Hudson Coal Co.

*Special to Coal Age*

Scranton, Pa., Nov. 17.—Disregarding orders from both John L. Lewis, international president, and district officials of the United Mine Workers, the general grievance committee of the Hudson Coal Co. on Saturday called a general strike of the company's employees effective today. As a result, eleven of the company's collieries, employing 14,000 men, are idle. Eleven other operations, the employees of which are affected by the strike order, are operating, as the men voted to work despite the committee's order.

President Lewis today telegraphed from Texas, where he is attending a convention, and demanded that Rinaldo Cappellini, district president, and David Davis, international organizer here, exert every influence to settle the strike. Long pending grievances are blamed by the general grievance committee for the walkout. Officials of the Hudson Coal Co., in full page newspaper advertisements yesterday, appealed to the men to continue work, pointing out that the walkout was illegal in that it violated the contract between the union and the operators.

Surface indications demonstrate that the local union officials are unable to check the general grievance committees in their methods of handling grievances. The Hudson company strike has been threatened time and again during the past few months and only interference by the local officials prevented it. However, the alleged insurgent element in the organization dominated, and on Saturday the strike was called. Efforts are now under way by district officials to bring about special meetings of colliery local unions to rescind the strike action at each idle colliery. This method brought results in the recent Glen Alden general strike.

## Trent Company Reorganized

The present Trent Superfuel Co. is to be reorganized under new management, as the Superfuel Corporation of New York. It will at once begin the enlargement of the Newark plant to a capacity of 1,000 tons per day. Guy Standifer prominently identified with Pacific Coast shipbuilding interests, will be the new president, and Francis R. Wadleigh, former Federal Fuel Distributor and a prominent factor in the

## Practical Pointers For Electrical And Mechanical Men

### Locomotive Lamps Burn Out Because Circuit Supplies Two Voltages

Normally the Headlight Lamp Receives Only 9 Volts  
But When the Main Fuse Blows 87  
Volts Get to the Lamp

WHEN an electrical engineer works for a big mining company it is always difficult for him to make frequent trips to all of the mines he has in his charge. Another difficulty he has is to attend to all the troubles which are found when with much effort the infrequent visits are made.

Some men believe that most of the little troubles experienced by workmen are half imaginary and therefore should be forgotten, but here is a little story which shows how easily important details may be allowed to slide.

At one of our mines the locomotive men operating storage-battery locomotives complained that the headlight lamps were not satisfactory. Every once in a while, they claimed, the lights

Fig. 1—This Circuit Subjects Lamps To Excess Voltage

Thus arranged the fuse does not protect the lamp. When the fuse blows and the controller is on, the headlight receives an 87-volt pressure. The circuit through the controller and motor causes the lamp to burn out.

would burn out, and they would find themselves in darkness. Of course, this provoked them, especially when they were far inside the mines where new lamps were not available.

When I realized what severe service most locomotives experienced I was not surprised when the motormen told me that their lamps frequently burned out. These were the first locomotives to be used at this mine, and I therefore thought that the motormen were expecting too much from their headlight lamps. I assumed that they expected them to last as long as lights used in the shops and that the only trouble they had was that the lamps failed to meet their unreasonable expectations. Besides, when I first heard this story I was on another mission to the mine and therefore did not have much time to look into the trouble.

Fig. 2—How High Voltage Gets To Headlight Lamps

The supposedly perfect circuit in Fig. 1 now shows itself to be false. When the fuse is out the long end of the battery supplies voltage to the lamps and they pop.

However, I noted the complaint and took the first opportunity to visit that mine again. Much to my surprise the difficulty with the lamps had persisted, and the motormen had kept the old lamps so as to impress me by their number. I suppose I did not show enough concern on my previous visit, and they proposed to prove to me this time that they had not been making statements without justification. Sure enough they had plenty of old burned out lamps to show me and the requisitions for new ones were steadily increasing.

Apparently, something was wrong so a thorough investigation was started. One of the locomotives was nearby and the wires were traced from the battery to the headlights, the voltage was measured and proved to be correct and the lamps were lighted to their normal brilliancy. Where was the trouble? Everything looked all right. The lamps were receiving the voltage for which they were designed as testified by the

Fig. 3—Simple Change Corrects Lamp Circuit

By merely changing the connection of one wire from the load side of the fuse to the battery side the lamp is safe against high voltage coming from the other end of the battery whenever the main fuse blows.

voltage figure stamped on them. To prove that they would work satisfactorily at this voltage the electrician had previously connected one of the lamps to four spare cells, and it had been burning continually for over a month.

We were about to come to the conclusion that we had received a poor lot of lamps and that the only solution was to await the supply furnished on the next order in the hope that they would be all right. There wasn't much satisfaction in this idea because many consignments of lamps had been received and the results with all of them were the same.

Suddenly one of the motormen said something which was new. We had hounded every clue until I was sure we had not hit the right one and therefore anxiously picked up this last remark of the motorman. He said that his lamps burned out whenever he had an overload on his locomotive. Now how could this affect the lamps? We will see.

Fig. 1 shows the manner in which the battery, motor, resistance, controller and lamps originally were connected. Note that the lamp is connected near one end of the battery and the other terminal is connected to the load side of the main fuse. Now look at Fig. 2 and see what happens when the motor is overloaded and the main fuse blows. In that event, the motor stops, and before the controller can be shut off there is a circuit from the far end of the battery to the lamp through the resistance, controller and motor. Thus an 87-volt pressure is applied to the headlight. Bang goes the lamp and you can pick the pieces out of the headlight frame. So this is what caused the trouble.

It wasn't long before the circuits on all the storage-battery locomotives were changed over as shown in Fig. 3. Now when the fuse blows the lights remain on and do not burn out. E. E.

### Decrease in Rope Diameter Sign of Weakness

Most authorities on wire rope say nothing about inspection. A few mention that the number of broken wires which show up in so many feet of rope or in a rope lay is an indication of a reduction of strength. Only about one in ten point out that a decrease in overall diameter is another sign of weakness.

This feature was well illustrated recently at a shaft mine in West Virginia, where the rope broke while hoisting coal. The rope used at this shaft is a 1½-in., 6 x 19 plow-steel cable

with a hemp core. In the regular inspections attention was directed to the items of lubrication, broken wires, and visible wear. The last inspection, made just before the break, disclosed the following conditions: Apparently the rope was well lubricated; there were no broken wires in sight; and the visible wear on the outside wires, due to friction on the drum and head sheaves, was not of sufficient magnitude to cause alarm.

#### BROKE UNDER NORMAL LOAD

In view of the apparent good condition of the rope it was a great surprise to have it break, and especially so while operating under normal load.

#### Hemp Core Almost Gone

Section drawings of the same piece of rope, one at a point near the break and the other a few feet from it. Deterioration possibly might have been detected by the reduction in diameter.

The actual break occurred in that part of the rope which was in contact with head sheave when the attached cage was at its lowest position. An examination of the broken rope showed that for a distance of approximately 10 ft. on each side of the break, the

hemp core had been crushed to pulp, and that many of the inner wires had been materially reduced in section by corrosion and wear of the strands against one another.

#### DIAMETER OF CORE REDUCED

Naturally, the question then arose as to how this weakened condition could have been detected by inspection. During the investigation the rope was calipered at several points. The end sections were found to have retained practically their original diameter of  $1\frac{1}{2}$  in. and in those sections the hemp core looked as good as new. However, that part of the rope, extending about 10 ft. each side of the break, was found to have been reduced in diameter to  $1\frac{1}{8}$  in.

It will appear that if this reduction in diameter which was almost  $\frac{3}{8}$  in., had existed prior to failure it might have been noticed by the inspector. However, unless suspected it is likely that he would not have detected it because of the rather gradual taper toward the point of smallest diameter.

Repeated shocks not one of which would be sufficient to cause fracture may result in the failure of a rope. Suddenly applied loads approaching the elastic limit eventually tire out a rope and yet do not reduce its diameter until sometime a load, which ordinarily would not cause fracture, breaks it.

Nevertheless the experience in this particular case indicates that a thorough inspection, to determine the service conditions of hoisting rope, might well include measurements of the rope diameter.

mine track, as shown in the accompanying illustration. Brick walls and steel girders are used to support the roof.

### One-Piece Brake Shoe Has Many Advantages

In spite of the many good features of a brake shoe and head cast into one piece, many of the repairmen at the mines have not had an opportunity to use them. In the sketch is shown the general outline of such a shoe. Usually it is made of cast iron or cast steel.

#### No Fussing with the One-Piece Locomotive Brake Shoe

Only one pin is required to hold this shoe in place, no adjustments of course are necessary to replace an old shoe with a new one.

Sometimes it is made with carborundum or steel inserts. Carborundum inserts should be placed so that they will grind off false flanges and keep them from forming. When steel inserts are cast into a shoe they are primarily intended to prevent the shoe from wearing too quickly.

#### SHOE FITS ANY WHEEL

No matter of what material the one-piece shoe may be made or whether it has inserts or not, it has the one advantage that it may be used on any of the four wheels of the locomotive, no rights or lefts are needed. Keys, screws, pins and bolts require no adjusting on this type of shoe and therefore it is easy to place on the locomotive. An old shoe can be taken off and a new one installed merely by knocking out the holding pin and replacing it in the new shoe. The ease with which this work can be done and the savings in time and labor which result, quickly make it desirable to change from the two- to the one-piece shoe. The motorman can replace an old shoe even though he may be far inside the mines if only he has one available. The fact that he is not compelled to carry both a right- and a left-hand shoe is a big advantage to him.

One large company using many different types and sizes of trolley locomotives changed the brake rigging on some of its locomotives so that this shoe could be used. Now only one type and size shoe is suitable for over 150 of its trolley type locomotives. Storage-battery locomotives use much smaller wheels and require a different size one-piece shoe.

### Underground Shop Planned to Prevent Weakening of Roof

Where the mine roof is of such a nature that it requires much support, it is wise to build an underground repair shop much longer than it is wide, enlarging the inby end for the accommodation of a work bench, tools and supplies. The plan view of the shop might well have the form of a T with horizontal arms of such moderate length that the area spanned would not be great enough to weaken the roof and yet would be large enough to af-

ford ample space for work. A shop like that just described was constructed in the Federal No. 1 mine of the New England Fuel & Transportation Co., Grant Town, W. Va. It is used chiefly for the repair of the undercutters, jackhammers and other compressed-air machines that are used extensively in this mine.

Small jobs can be done on the elevated platform adjacent to the bench at the same time as big jobs are being handled in the narrow section of the shop. An overhead crane travels on an I-beam in a direction parallel to the

#### Tee-Ended Shop Convenient as Well as Safe

This shop has an unusual shape but apparently the design is well chosen, for it gives more working space and a more effective reach to the crane without necessitating greater floor space and without making it necessary to support the roof with pillars.

# Production And the Market

## Expected Upturn in Coal Market Slow to Appear; Prices Cease Downward Course

Rough weather is the missing element for which the coal trade now hankers, for business has practically settled down to a weather proposition. In some quarters the waiting policy adopted by consumers was attributed to a supposition that a revival hinged on the outcome of the election, but the upturn that was expected to follow the re-election of President Coolidge has been of minor consequence thus far. As a matter of fact the general business situation shows an improvement, as reflected in heavier production and larger orders for steel, continued gradual gains in textiles and increased exports. Overseas coal shipments, however, have fallen off badly. Car loadings continue well above the million mark, but one of the most encouraging factors is the large volume of orders for rolling stock being placed by the railroads.

### Trade Lives on Hope

Though basic conditions are sound and sentiment is noticeably better, the trade is getting little nourishment in the way of actual returns, simply hanging in the belief that a taste of real winter will bring lagging consumers into the market with a rush. The ubiquitous Mr. Ford has broken out with a scheme for unloading coal from his Kentucky mines in the Northwest, and though not much is expected to come of it this year the dock operators are not exactly overjoyed at the prospect later on.

The hard-coal business continues a disappointment, demand being slow in the face of appeals and warnings to consumers against procrastination. The call for stove and chestnut holds steady, but egg and pea are moving only with some difficulty. Steam coals are quiet, barley being the best of the lot and No. 1 buckwheat the worst. Independent prices are holding their own fairly well, despite the recent boost in quotations.

Coal Age Index of spot prices of bituminous coal, after slipping for two weeks, came to a halt during the

last week, standing on Nov. 17 at 170, the corresponding price for which is \$2.06, the same as the week before.

Activity at Hampton Roads registered a slight gain last week, dumpings of coal for all accounts during the seven-day period ended Nov. 13 totaling 356,603 net tons, compared with 325,568 tons the previous week.

There was a further increase in the movement of coal up the lakes, dumpings at Lake Erie ports during the week ended Nov. 16, according to the Ore & Coal Exchange, being as follows: For cargo, 753,405 net tons; for fuel, 30,875 tons compared with 704,538 and 30,937 tons respectively during the previous week.

Holidays again caused a decline in the production of bituminous coal during the week ended Nov. 8, when, according to the Geological Survey, 9,322,000 net tons was produced, compared with 10,065,000 tons in the preceding week, as shown by revised figures. The curtailment was due to the observance of All Souls' Day and election day. Allowing for the reduction in working time, the daily output actually was larger than during the previous week. Anthracite output, on the other hand, increased slightly during the week ended Nov. 8, 1,592,000 net tons having been produced, a gain of 148,000 tons over the preceding week, when the observance of Mitchell day cut heavily into production.

### Estimates of Production

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

## Midwest Idles Along

The weather simply is not rough enough for Midwest coal producers. Nothing else can be counted on to increase business and so nobody is inspired about trade. Of course there is some lump and egg business stringing along, but it is not large and most mines are unable to get more than three or four days a week and are troubled with fine coal even at that low production. Industrial pick-up is slowly going ahead but coal in storage and coal that has been contracted for the winter take care of about all the steam demand there is. Lump prices maintain themselves fairly well in most Illinois and Indiana fields but egg and 2-in. lump wobble. Even fine coal gets into distress these days.

West Kentucky is getting some trade throughout the Midwest and Northwest so that its output is cutting a considerable figure in steam and second class trade. Eastern Kentucky is moving into this territory in slightly larger volume because producers there see the end of the Lake season and are making extra efforts to sew up business elsewhere. They anticipate a real advantage over Midwest coals when the new lowered freight rates from the inner crescent region take effect. Pocahontas coal continues to move West in some volume but the tendency is toward price concessions, possibly because of the great amount of smokeless egg and mine run that reached the Midwest during the summer and early fall. No smokeless mine run

ever brings over \$2 now and most business is below \$1.75. Lump and egg has dropped from \$4.50 to \$4 as a minimum.

In southern Illinois railroad tonnage is unusually light. Mines are working from one to four days a week, depending upon this business. At a few of the biggest mines in southern Illinois there are mountains of screenings piled up on the ground, but this is about to end, for the cost of storing together with the cost of coal is running into figures that are amazing and there is always a danger of spontaneous combustion causing perhaps an entire loss. Some mines will suspend operations soon if conditions do not improve. Somewhat similar conditions prevail in the Duquoin and Jackson County fields except that no screenings are stored. Working time is poor and there is no market.

In the Mt. Olive district the movement goes with the temperature. A little coal is moving but nothing to speak of excepting railroad tonnage to the Northwest and a little steam and domestic to the Kansas City and Omaha markets. In the Standard field conditions are about as bad as they can be. Screenings have gone up to 75c., but 2-in. lump is down to \$2.20 and the other sizes are dragging.

## Weather Is Hard on Kentucky

Although a good many Kentucky mines are fairly well sold up, some cheap tonnage is being offered, jobbers running into direct sales of mines at as low as \$2.75 on Harlan block coal, whereas some of the good mines are asking

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

Index	1924			1923
	Nov. 17	Nov. 10	Nov. 3	Nov. 19
Weighted average price	170	170	171	183
	\$2.06	\$2.06	\$2.07	\$2.21

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

\$3@3.50 for prime block coal. However, there isn't much block moving at over \$3@3.25 due to mild weather and heavy production. It is believed that with cessation of Lake movement the heavy production of West Virginia and Kentucky non-union mines will meet with harder competitive conditions, which may make for slightly weaker prices, unless there is some really cold weather soon. Demand, which had been expected to improve right after election, hasn't picked up much as yet. Western Kentucky block and lump sizes have been a little weaker as a result of larger production, good traffic conditions and mild weather. Screenings also are about 10c. a ton higher than they have been, as a result of lighter production of prepared sizes. Mine run is rather draggy. Operators have been developing a better demand for small steam nut sizes, and almost all screenings are now being run down to pea and slack.

Despite the strike in Muhlenberg County, output in western Kentucky is around 55½ per cent of capacity. Prices show 6-in. block coal, \$3; lump and egg, \$2.50@2.75; nut, \$1.60@2.25; mine run, \$1.50@1.75; and screenings, 75@85c.

#### Northwest Has Some Cold

At Duluth cold weather and a touch of snow have had a salutary effect on the coal market and the docks are now working full time getting out orders. Features of the market are the failure of the supply of Pocahontas lump and the sharp drop in hard-coal receipts. Pocahontas is literally sold out in desirable sizes. The supply of hard coal is large, but there is little demand for it as yet, except from Dakota, which has come into the market stronger than in five years; nevertheless prices hold firm. Bitu-

minous holds as quoted last week. The general trend, however, is for strength.

Last week 37 cargoes were received at Duluth, of which one was hard coal, and 10 are reported on the way, of which only one is anthracite.

Cold weather has finally arrived in the Twin Cities and has helped to start long delayed buying. But unless the cold weather continues for a few days the effect will be short-lived, as the habit of buying for urgent needs only is not easily overturned. Dock prices are holding steady at former prices. All-rail prices are somewhat firmer, with southern Illinois lump at \$3.25@3.50, western Kentucky lump \$3 and central Illinois lump \$2.75.

Last week's Milwaukee report covers the situation there today. Coal is coming to Milwaukee quite steadily but it is not moving out again as freely as dealers would have it. Colder weather is needed. Receipts by lake and rail up to Nov. 1 total about 1,000,000 tons less than for the same period last year, but there was a holdover of about the same amount last spring.

#### West Depends on Weather

Demand in the Southwest continues weak, but so close has been buying by retailers that brief cold spells produce immediate orders. Prices are a bit firmer than last week. There is small surplus of screenings, as the slump in demand for domestic grades afforded an opportunity to rid tracks of oversupply accumulated early in the season.

A slight decrease in domestic coal output was noticed last week in Colorado, due to continued warm weather. However, it seems reasonable to believe that with the first spell of winter weather everyone will be extremely busy because of low stocks. Colorado mines worked 31 hours last week with 24 per cent of working time lost attributed to "no market." Prices have not changed since Oct. 20.

A cold snap in Utah has increased coal production in that state, but average working time is still only around three and a half days a week. The demand in regard to sizes of coal is well balanced again, but there is a slight tendency to a shortage of slack.

#### Softness Prevails in Ohio Markets

Cincinnati yearns for a touch of cold weather. The market is soft, slack and mine run being about the only sizes able to hold their own. Car interchange fell off nearly 1,000 during the week. Smokeless business is feeling the effects of the slowing up with New River, Dry Fork and other of the coals in this category selling below standard Pocahontas. The long dry spell has hit river business hard and practically all the retailers have caught up on orders. Some are offering inducements to encourage buying.

Both the domestic and steam trades are exceedingly dull at Columbus. Dealers are waiting for lower temperatures before placing orders and steam users also are playing a waiting game. Prices have weakened perceptibly and production also has suffered. Cancellation of orders placed during the short boom of several weeks ago is throwing much distress coal on the market. Pocahontas and other smokeless varieties are weaker and a price decline of 25c. a ton is reported. Splints also are weaker. Utilities are using a fair tonnage and railroad consumption is slightly better, but general manufacturing has not improved to any extent. Screenings are weak because of the large output and the fact that lake trade is nearly ended.

While no significant change has taken place in the demand for bituminous coal at Cleveland there is not as large a quantity seeking disposition as there was a week ago, and because of this, spot prices have rebounded 5c. to 10c. from the extreme low figures of last week. The mild weather has cut into lump production and the Lake shipping from the mines is dwindling. These two factors have caused a reduction in the quantity of slack being produced, inquiries for which are rather active.

#### Selling Difficult at Pittsburgh

Demand for coal at Pittsburgh has increased only slightly since election. Accumulation of coal on track has caused curtailed production at many mines. Consumers having arrangements for regular shipments have been taking coal much the same as formerly, but the open market demand has been very poor. Prices remain stationary despite the extreme difficulty of effecting sales.

The situation at Buffalo does not change much. Considerable coal was shipped here just before election by

sanguine operators, with the idea that the election alone would have sufficient influence to effect a sale of it. It did not. Shippers complain that the demand is not as good as it was last month. The principal reason is absence of cold weather. The Canadian trade is still poor. Some jobbers are staying out of it, for they say prices have to be very low to compete with Dominion coal. Little is doing in the lake trade.

Demand at Toronto is somewhat better and is improving steadily. Pennsylvania smokeless sells for \$5.85, steam lump at \$6.40, and slack at \$5 in carload lots, delivered.

### New England Yearns for Industrial Pick-Up

If anything, the New England market is easier and buyers are less in evidence. Certainly the Hampton Roads agencies have about given up hope of higher prices for the present, so few sustaining factors are there in the current market. Industrially there is no snap, and more than a few lines of business are muddling along with no bright prospect. Recent purchases of textile plants by rubber tire producers have caused comment, but the mills acquired are relatively small and the change in ownership will have little effect on cloth manufacturing as a whole. Meanwhile, steam coals are only in light request.

At Hampton Roads there are again small accumulations, but as yet there has been no pronounced dip in price, \$4.25 @ \$4.40 continuing about the range for Navy acceptable grades, with No. 2 coals selling off to the extent of 15@25c. Slack can still be had at minimum figures, and of this there is a fair amount of buying by consumers with automatic stokers. Offshore there is mild inquiry in response to the slight improvement in British trade, but not yet have there been purchases of any magnitude. What this year amounts to an average coastwise movement is about all that can be said for trade in this territory.

For inland delivery at Boston \$5.40 @ \$5.50 is about the present level on cars, with Portland and Boston commanding figures a trifle higher. Pocahontas and New River have the call from points well into the interior.

No developments can be seen in coals from central Pennsylvania; prices are on a cost basis.

### Atlantic Markets Quiet but Hopeful

General industry has not picked up sufficiently to increase the demand for soft coal at New York. Buyers continue to view the situation at a distance and are buying only for immediate requirements. Consumption is practically at rock bottom. The situation along the line and at tidewater shows comparatively no change from last week, either in prices or demand. Receipts at the piers show an increase in the average number of cars on hand and as a result there has been an oversupply at times, but not enough to drive prices to a lower level. Some consumers are taking one or two car lots when the price and quality of the coal are right.

The Philadelphia trade is more hopeful; inquiries are heavier and a larger proportion than usual is developing into orders. Consumers who have been buying at the market for months are inquiring as to contracts and a fair amount of business has been closed to April 1. General business conditions seem to be looking up. There is still a good supply of slack, due to the increased screening of coal, especially of the gas grades. The market at tide continues quiet.

The Baltimore coal trade is optimistic. The passing of the election followed by a brisk rise in the stock market leads

some coal men to believe that money will be released for industrial development, and that this will tighten up the coal trade. Meanwhile demand is only fair and prices are extremely low. Exports for the first two weeks of November have fallen far behind the same period of October.

The Birmingham market shows no material change. Domestic trade is suffering on account of adverse weather, both the wholesale and retail movement being slow and consumers showing indifference. There is a fairly good demand for steam, comparatively speaking, but neither inquiries nor sales are up to normal for this season. Prices in the steam market are unsatisfactory, affording a small margin of profit to the mines. Output for the week of Nov. 1 is reported as 355,000 net tons. Industrial conditions generally are showing a more favorable aspect since the election.

### Anthracite Markets Suffer Setback

The anthracite market at New York lacks activity. There is a steady demand for stove and chestnut coals but producers find it difficult to dispose of egg and pea sizes easily. The situation is dull, notwithstanding the appeals sent out to consumers to stock up while coal is available. Weather conditions are against consumption and consumers are not willing to buy until forced to. There is not much activity in the steam coals, No. 1 buckwheat lagging the most. Barley is in the best shape.

The retail trade at Philadelphia lost much ground this week, due to continued mild weather. Producers have practically enough orders on their books to absorb output, due to the October shortage. Egg is weakening, pea shows signs of dragginess and the demand for stove is beginning to run off, but nut is moving well. There are signs of weakness in the retail price situation, despite the fact that independent mine prices have generally risen.

Anthracite business at Baltimore continues rather listless because of the continued mild weather and the fact that many householders have now adopted the plan of buying in two-ton lots over the winter, as coal is needed, instead of placing in entire stocks in the fall or early winter. In order to combat oil-burning devices the trade is arranging to exhibit a buckwheat-burning furnace with mechanical blower attached. The yards are fairly well stocked.

Demand at Buffalo accords with the weather. Probably not more than half the amount of anthracite has been laid in here by consumers since last spring that ordinarily goes in in the same time. The families are burning natural gas, the schools and quite a good many other plants that once used anthracite to cut out the smoke, are using smokeless coal and they will never go back to the old fuel. The anthracite companies urge the use of small sizes, but are doing nothing, at least here, to introduce it. The demand for coke is as light as ever.

Owing to the prolonged spell of warm weather, demand for hard coal at Toronto is rather light. Anthracite is still retailing at \$15.50 and in plentiful supplies, but there is some scarcity of stove coal. No shortage is expected this winter, though.

## Foreign Market And Export News

### British Steam Coal Trade Perks Up; Output Above 5,000,000 Tons

The Welsh steam coal market has brightened somewhat, though a considerable extension of the present business is necessary before the market can be restored to normal. European inquiry has expanded, coaling depots abroad are showing a greater interest, and there also has been inquiry from other directions. The business booked, however, is not sufficient to keep the collieries busy, and during the past week 6,000 more men were thrown out of work. Curtailed output in conjunction with the slight increase in business has enabled the operators to maintain their prices.

The French Ministry of Marine is in the market for 43,000 tons best Admiralty large.

The Newcastle market has had a relapse from last week, and is flat and depressed. Shipments are very slow and operators are taking low rates for their coal. The Lithuanian State Railways are asking for 30,000 tons of steams, but otherwise there is no business to speak of. German competition abroad is keenly felt and the outlook is generally regarded as very unsatisfactory.

Production by British collieries during the week ended Nov. 1, a cable to *Coal Age* states, totaled 5,043,000 tons, according to official reports. This compares with 5,061,000 tons produced during the preceding week.

#### Hampton Roads Market Quiet; Foreign Trade Declines

The market at Hampton Roads is quiet, with bunkers and coastwise business only fair and with foreign movement rapidly on the decline. Nothing but extremely cold weather would give the market any stimulus, in the opinion of the trade.

Prices have softened and supplies at tidewater are somewhat lower, due to

lack of movement from the mines rather than to movement over the piers. The outlook for an immediate pick-up in business is not considered bright.

The tone of the market is dull, high-volatile coal alone holding its own. Inquiries have slumped and the spot market is more inactive than for the last six weeks.

#### French Markets Change Slightly As Mild Weather Lasts

The French industrial and domestic coal markets are practically unchanged since the beginning of the autumn. Due to mild weather, the consumption of house coals is low and some varieties of smalls and screened fuels are easier because of lack of demand. Imports from South Wales have been lower of late. Deliveries of semi-bituminous and sized products from Belgium, however, show a little more animation.

Canal freight is maintained at 25 fr. Béthune-Paris and 9.75-10 fr. Rouen-Paris.

Deliveries of indemnity fuels during the first twenty-six days of October to France and Luxembourg were 406,800 tons of coal, 288,800 tons of coke and 31,800 tons of lignite briquets, a total of 727,400 tons.

From Oct. 1 to 28 the total supply of coke to the O.R.C.A. amounted to 253,349 tons, a daily average of 9,050 tons. The M.I.C.U.M. having ceased its functions in the Ruhr on Oct. 28, deliveries of coke on the 29th were only 1,855 tons through Ehrang and 5,207 tons through Aix and on the 30th 1,576 and 2,917 tons respectively, a total of 11,555 tons for the two days. Since the 30th the German supply of reparation coke has practically stopped. French metallurgists, however, have enough fuel to live on until the fixation of the delivery programme by the Reparation Commission. If France's claims are

recognized she will get a supply of from 300,000 to 400,000 tons a month.

The output of coke in the French northern collieries is being intensively developed. The Courrières coal pits, where coke production has been hitherto unknown, are erecting 90 ovens of a capacity of 140,000 tons a year; 140 new ovens are under construction at Lens; the Noeux collieries are raising their annual production by 120,000 tons while the Aniche mines will hereafter produce 300,000 tons of coke annually.

## News Items From Field and Trade

### ALABAMA

The consummation of the merger of the properties of the Sloss-Sheffield Steel & Iron Co. and the Alabama Company awaits only the ratification of the directors of the respective companies, such approval being expected this week.

Rumors are current in the Birmingham district that important developments in the way of additions and betterments at local plants of the Tennessee Coal, Iron & Railroad Co. will soon be announced.

The Edgewater mine of the Tennessee Coal, Iron & Railroad Co., the largest colliery in the Alabama field, produced a record tonnage of 127,825 tons in October as against record of 104,562 tons mined in August. The blast furnaces of the Tennessee company broke all previous records with an output for the month of 127,925 tons.

### COLORADO

The Rocky Mountain Fuel Co. is said to be concentrating its production largely in the Columbine mine, in the northern Colorado field, and in the Southwestern mine, near Aguilar, in the southern part of the state.

The Bluff Springs Coal Co., which has worked one or two properties near Canon City, is about to open the old Donnelly slope near Coal Creek. The mine has been rehabilitated and electrified.

Fred Farrar, according to newspaper reports, is to retire as executive vice-president of the Colorado Fuel & Iron Co., to re-engage in general practice of law, but will continue as general counsel for the company. The announcement comes from President J. F. Welborn. Mr. Farrar is one of the foremost members of the Colorado Bar. He has been practicing law in the state twenty-three years. From 1913 to 1916 inclusive he was Attorney General of the state. In July, 1918, he became general counsel for the Colorado Fuel & Iron Co.

Local strikes have caused some lost time recently in the Walsenburg region. At Morning Glory mine the men struck rather than pay \$2 for the recharging of cap lamps. At Pictou the force walked out because two men were fired for inhumane treatment of a mule.

The Colorado Fuel & Iron Co. in a movement toward concentration of production, has closed three mines in the Trinidad field employing over 600 men and producing approximately 50,000

tons of coal per month. The mines are Sopris No. 2, with a personnel of about 317 men and a monthly production of 25,000 tons; Tabasco, 193 men, 17,000 tons monthly, and East Side Primero, with 92 men. The entire Primero mine produced about 13,000 tons monthly; East Side was the major operation.

The Victor American Fuel Co. has just reopened Radiant mine, in the Canon City field, in Fremont County. Radiant, a commercial producer, has been closed since last March. It employs 150 miners.

### ILLINOIS

The Benton Coal Co. has opened its No. 1 mine near that city and will operate steadily, employing between 500 and 600 men. The mine is one of the first in the Benton district to resume work.

Harry F. Goodnow, formerly chief mining engineer for the Majestic Coal & Coke Co., and later superintendent of the Crerar-Clinch properties at Johnston City, is now connected with the Gayle Coal Co., at Du Quoin, a new stripping operation operated as a subsidiary of the two former concerns.

The large wash house at Mine No. 14, Old Ben Coal Corporation, Buckner, was destroyed by fire last week. The building was constructed of brick, with a tile roofing and was considered almost fireproof. Officials of the mine are at a loss to determine the origin of the fire.

The records of both Zeigler mines were again broken in October with a total production of 313,644 tons. Zeigler mine No. 1 has produced in the last eighteen years a total of 12,632,615 tons.

Two Williamson County strip mines in the vicinity of Cartersville have been reopened upon a full time schedule. Weaver mine No. 20 plans to resume operations soon, after having been closed down since last November.

A cage at Orient No. 2 mine of the Chicago, Wilmington & Franklin Coal Co., loaded with thirty-six miners was dumped at the top of the tippie Nov. 7 at the end of a day's work, throwing the men into the weigh hopper about 30 ft. below. Only three men were injured seriously enough to require hospital attention.

John Meyer, assistant foreman of the large Kathleen mine of the Union Colliery Co., at Dowell, has resigned on account of ill health, and has gone to St. Louis to live with his family.

### INDIANA

H. Clarence Bean, formerly with the Jewel Coal & Mining Co. and the Sterling-Midland Coal Co., with operations in Illinois, has been made general superintendent over three mines of the Coal Bluff Mining Co., at Terre Haute. The three mines are all in operation at present.

The Brazil Collieries Co., at Brazil, has filed a final certificate of dissolution.

The Wheatland Standard mine, at Bicknell, which has been closed down for several weeks in a controversy over the installation of a loading machine at the mine, probably will resume work soon, officials say. As a result of a conference held in Indianapolis last week, at which Wheatland miners were delegates, it was agreed that the mines keep the machines in operation during the testing stages. Later a meeting will be called to arrange a permanent wage scale.

Fire which was discovered Nov. 7 in the Indian Creek mine, at Bicknell, has caused the sealing of the mine with the possibility that it will not work again for many weeks. The men working at the mine "skinned up" and the fan was stopped Friday night to permit a change from steam to electric power. On Nov. 11, however, the mine boss discovered the fire and also evidences of an explosion. In a way it is believed to have been both harmful and helpful that the fan was down. Had it been operating, it probably would have blown out the smoke and caused the fire to be discovered sooner. But, had it furnished oxygen to the explosion, it might have caused a blast of much greater proportions.

D. C. Stephenson, former grand dragon of the Ku Klux Klan in Indiana, has announced the sale of the Central States Coal Co. to L. G. Julian, of Evansville, for a total sum, he said, of \$200,000. He has accepted a position as general manager of a New York firm at a salary of \$25,000, he said. He refused to give the name of the company. He said also that he had caused to be written into the contract for the sale of the company a provision that the company could not sell its product to the state during the term of the next Governor.

Carl J. Fletcher, vice-president of the Knox Coal Mining Co., has been named receiver for the J. & I. Coal Co., of Indianapolis. The appointment was made on petition of the E. & J. Coal Co., plaintiff in a suit to foreclose a \$3,500 mortgage on the J. & I. property. The appointment of a receiver

was asked pending hearing of the suit. Owners of the defendant company are John D. Johnson, Willard E. Jackson and Catherine Shearman.

## KANSAS

A further effort to lay the Alexander Howat ghost in District 14, United Mine Workers, is contained in a letter by the district board to locals, reiterating the recent warning by President Lewis that Howat is ineligible for the presidency of the district and declaring that Howat's name and the names of his associates will not appear on the ballot for the December election. Many locals have disregarded Lewis's message and have placed Howat in nomination for the office. In its supplementary letter the board warns of the possibility of the district again losing its autonomy, as it did in 1921, following the outlaw strike called that year by Howat, then president, and his associates.

## KENTUCKY

L. W. Fields, of Lexington, and associates have purchased a large tract of coal and timber land in Letcher County.

Shelby Elliott, 26, president of the Big Four Coal Co., Louisville, is recovering from injuries received in a recent motor accident in which a car that went dead blocked the road and caused a triple collision in the dark.

Forest fires in Kentucky have caused a great deal of damage and some of the coal companies have lost a lot of timber, but no mine buildings have been burned. Early frosts were followed by weeks of dry weather, and the country was brown and dry. The West Kentucky Coal Co., in western Kentucky, is reported to have suffered some timber loss.

The Elkhorn Coal Co. is about to begin erection of a \$20,000 store building in Master.

The Hamilton Mining Co., Cromwell, Ohio County, western Kentucky, recently reported that cables furnishing current to the mine had been cut during the night of November 4, putting the mine out of commission until the

breaks were located and splicings made. The company is operating in spite of the union strike in nearby Muhlenberg and Hopkins counties.

## OHIO

The tippie of the Eagle Coal Co. mine, south of Zanesville, was totally destroyed by fire recently, entailing a loss of about \$75,000. All of the equipment was destroyed and the mine will be out of commission for some time. The flames caught from a fire in a woods adjoining the tippie.

Officials of the Middle States Coal Co., of Columbus, are making an exhaustive investigation of the dynamiting of tipples No. 24 and No. 68 on its property in the Hocking Valley, which occurred several weeks ago. One of the tipples together with the power plant and all equipment was totally destroyed. Arrests will follow if the investigation reveals the culprits.

## PENNSYLVANIA

Lee, Higginson & Co. and Cassatt & Co. are offering a new issue of \$5,000,000 South Penn Collieries Co. first mortgage sinking fund Series A 6 per cent bonds, due Nov. 1, 1944, at 94½ and interest, to yield over 6½ per cent. The bonds are secured by a first mortgage on all fixed properties and leaseholds of the company.

Directors of the Glen Alden Coal Co. have declared a dividend of \$3.50 a share, payable Dec. 20 to holders of record Nov. 29. An initial dividend of \$1.50 a share was paid Dec. 20, 1922. A payment of \$2 was made June 20, 1923, and one of \$2.50 was made Dec. 20, last year. On June 30 last, \$3.50 a share was paid.

Announcement has been made that the firm of Peale, Peacock & Kerr, Inc., leading coal operators in central Pennsylvania, with offices in Philadelphia and New York city, have purchased from Mrs. Anne W. Penfield, of Philadelphia, formerly of Williamsport, 5,000 acres of coal land holdings in English Centre, Lycoming County. The engineer's report shows that there are 30,000,000 tons of bituminous coal under the sur-

face of the land bought and it is proposed to mine the coal and market it by building a railroad from the mines to Cedar Run, on the New York Central R.R. Mrs. Penfield still has 10,000 acres of coal land in the same vicinity. Rembrandt Peale, senior member of the purchasing firm, resides in St. Benedict, Clearfield County.

Robert H. Lansburgh, new Secretary of Labor and Industry, in announcing his policy for the conduct of his department, notified inspectors that they must devote seven hours to actual work a day five days a week and three hours on Saturday. Inspectors were told they can recommend any safety devices indorsed by the department and the State Industrial Board, but that they may not pick out any one device for special recommendation.

The Wolfe Coal Co. will soon open a new stripping operation near its mines between Lattimer and Drifton and has awarded the contract for the operations to the Schraner Construction Co., of Scranton. A steam shovel will be moved from the present operations to the new job next week.

Committees representing each of the five Pennsylvania districts, United Mine Workers, were appointed at a meeting at Harrisburg, Nov. 12 of the various executive committees, to study the mining laws with a view to making certain recommendations to the next Legislature. The committees are to determine what legislation, in their opinion, is needed and report at a general conference prior to the meeting of the General Assembly. The conference date will be determined later.

Orders have been issued to blow in immediately 340 additional ovens at the H. C. Frick plants at York Run, Phillips, Collier, Continental No. 1 and Hecla. It is understood that more ovens will be placed in operation soon.

The Mahanoy Valley Coal Co., idle the past few months, has resumed operations at its washery at Girardville, adding another feeder to the tonnage which the Hazleton & Mahanoy Division of the Lehigh Valley R.R. sends to the anthracite markets.

## UTAH

J. A. Stallings, sales manager of the Spring Canyon Coal Co., who has been seriously ill for some months, is much improved and is now able to spend a short time in his office each day.

L. C. Karrick, a Salt Lake City engineer, has been appointed to take a part in the research work started by the Carnegie Institute of Technology which has for its purpose the elimination of the smoke problem in large cities.

George H. Dern, who has been chosen next Governor of Utah, is a prominent Salt Lake City mining engineer.

Sam Woodhead was re-elected county commissioner of Carbon County over T. A. Stroup, superintendent of the Clear Creek mines of the Utah Fuel Co., at the Nov. 4 election by a plurality of 393. Mr. Stroup was at the disad-

Main Haulage Road at No. 1 Mine North-East Coal Co.

This steel bridge has been constructed on the main haulage road between the "High Bridge" opening of No. 1 Mine and the older part of that mine, near Thealka, Ky. The steel section of the bridge is 600 ft. long. Wood approaches, 54 and 56 ft. long, have been built at either end. At the highest point the rail is 116 ft. above the fertile valley. This is the highest mine-car trestle in eastern Kentucky.

vantage of being on the Democratic ticket in a strong Republican year. However two other Democrats were elected to the commission for short terms. George H. Dern, a Democrat, beat Gov. Charles R. Mabey, Republican, both in Carbon County and in the state, and therefore takes the executive chair.

The United States Fuel Co. has appointed R. W. Sheppard district sales manager with offices at Portland and Seattle. Mr. Sheppard is a North-western man and has had considerable experience in the coal business.

William C. Stark, manager of the Citizens Coal Co. of Salt Lake City, and former president of the Utah-Idaho Retail Coal Dealers' Association, has been elected a member of the state House of Representatives. Mr. Stark was a member of the last Legislature. Elias S. Woodruff, who was a partner in the recent Woodruff-Sheets-Morris Coal Co., also has been elected to a seat in Utah's legislative body.

The Rains mine of the Carbon Fuel Co., which was wrecked by an explosion in September, resulting in the loss of five lives, has been reopened. The official report on the cause of the explosion has not yet been made.

## WEST VIRGINIA

Officials of the union in southern West Virginia make no secret of the fact that although a few years ago the United Mine Workers had about 50,000 members in West Virginia, its membership is now less than 15,000, 12,000 of whom are employed in northern West Virginia mines. Union officials are inclined to blame their loss of membership on existing economic conditions.

Although seriously injured, suffering from a fractured skull and four broken ribs, sustained in an accident, it is believed that W. T. Hughes, president and general manager of the Fort Grand Coal Co., operating in Monongalia County, will recover. Mr. Hughes, with several employees had gone to a voting place in the county and was turning his car around when it slipped over a bank to the bed of a creek 60 ft. below. Only last July Mr. Hughes suffered a broken leg in an accident and had only recently been able to discard crutches.

When 18 or 20 miners ceased work and joined the United Mine Workers at the plant of the Sitnek Coal Mining Co., at Lumberport, in the Harrison County field, on Nov. 7 there was a temporary cessation of operations but it is stated by officials of the company that the Katherine mine was working as usual the following day with 50 miners. The company also states that it is still producing from 9 to 10 cars of coal a day. The officials of the union on the other hand claim that 100 miners at the plant are organized and that not more than 15 miners remain at work.

Eviction suits brought by the New England Fuel & Transportation Co. to gain possession of a number of houses at Everettville, in Monongalia County, have been settled out of court under an agreement with counsel rep-

resenting the coal company and the United Mine Workers. Originally the suit was brought against 37 occupants of company houses, but since the time of filing the suit fourteen families have moved, leaving 23 who are covered by the agreement, which provides that the miners remaining in possession of company houses shall vacate on or before Jan. 5, 1925.

In connection with the semi-annual meeting of the West Virginia Mining Institute to be held on Dec. 3 at Welch, a first-aid and mine-rescue contest is to be staged with at least forty teams from Mercer and McDowell counties participating. Only a few days ago W. H. Forbes, assistant mining engineer in charge of work for the U. S. Bureau of Mines in West Virginia, returned to his headquarters at Huntington from the Pocahontas field, where he had been assisting in making preparations for the first-aid contest, which is to be in charge of C. C. Morfitt, secretary of the Tug River Operators' Association, assisted by Joseph Reed, safety director of the Consolidation Coal Co. and president of the West Virginia Mining Institute. R. M. Lambie, chief of the department of mines of West Virginia, has been in the Pocahontas field for several days in preparation for the first-aid contest.

## WYOMING

Having this summer completed water systems for the company camps of Hanna and Winton, the Union Pacific is now constructing a new water system for Reliance. The new wells also will supply the Union Pacific R.R. switching locomotives with water, relieving a drain on the Rock Springs system.

## CANADA

The Coal Creek Collieries of the Crows Nest Pass Coal Co., have been closed down indefinitely. W. R. Wilson, president and general manager of the company, explains that lack of trade makes continuance of work at present out of the question. It is understood that the Michel Collieries are to continue production. The company's decision throws 750 men out of work and the provincial government has sent a deputy Minister of Labor to inquire into the situation.

The Western Fuel Corporation of Canada has moved its sales office from Nanaimo, where it was established more than 70 years ago, to Vancouver. J. G. Lawrence is the general sales manager and W. A. Webb, formerly agent for the company in Vancouver, has been made assistant sales manager.

The Princeton (B. C.) Collieries, Ltd., which absorbed the Princeton Coal & Land Co. eight months ago, has uncovered a 22-ft. seam of bituminous coal.

The government of Alberta has appointed a commission to make a comprehensive survey of the coal industry of the province, including methods of marketing on the prairies. The commissioners are H. M. E. Evans, who is largely identified with the industry in

northern Alberta, chairman; Robert C. Drinnan, director of the Mountain Park and Luscar Collieries, representing the operators, and Frank Wheatley, president of the Alberta Federation of Labor, Blairmore, representing labor.

The existence of coal deposits in the Sudbury district of Ontario has been known for many years, but whether the field was commercially valuable has been a subject of much controversy. The government geologists who have made investigations usually have taken an unfavorable view. The Colonial Coal Co., of Toronto, after preliminary diamond drilling, has come to the conclusion that mining can be profitably undertaken and is putting down a shaft. The progress of the work will be watched with much interest as a possible step toward the solution of Canada's fuel problem.

## New Companies

**The Cabin Creek Coal Co.** has been incorporated in Walch, Okla. by L. M. Green and H. E. Ryker, of Walch, and H. L. Cheyne, of Miami, Okla.

**The Glen Mary Coal Co.** James Building, Chattanooga, Tenn., has been incorporated with a capital stock of \$50,000 by H. B. Bonney, E. W. Elmore, J. F. Falzow and others and will acquire and develop property at Glen Mary, Tenn.

**The Saxton Blue Gem Coal Co.** has been incorporated in Saxton, Ky., by J. M. Persifull, James Percifull and others.

**The New Coal Co.** has been incorporated in Pineville, Ky., by M. M. Cox, H. I. Cawthern and M. Brandenburg.

**The Ohio River Edison Coal Co.** Knoxville Village, Ohio, has been chartered with an authorized capital of \$200,000 to mine coal and deal in coal and coke. Incorporators are Union C. DeFord, Donald J. Lynn, T. Lamar Jackson, Norman A. Enery and David E. Jones.

**The Diamond Clay Products Co.** Ironton, Ohio, has been chartered with an authorized capital of \$1,200 shares, no par value designated, to operate coal properties. Incorporators are M. P. Krag, Wm. H. Myers, H. S. Miller, W. H. Webb and Robert J. Beatty.

**The Cedar Grove By-Product Coal Co.** has been organized with a capital stock of \$25,000 to operate at Fred, W. Va., in the Kanawha field. Active in organizing this company were John D. Alexander, W. A. Alexander, Elizabeth Alexander, S. V. Morris and H. C. Ferguson, all of Charleston, W. Va.

## Industrial Notes

**The Fuller-Lehigh Co.** has entered into an agreement whereby everything in connection with its pulverized coal business will be handled in the various countries throughout the world by **Babcock & Wilcox, Ltd.**, of London, with the exception of the United States, its dependencies, Canada and Mexico.

**The Beaudry Co., Inc.**, manufacturer of forging hammers, recently moved into its new factory, on the Revere Beach Parkway, Everett, within three miles of the business center of Boston. The main building is 70 x 140 ft., of concrete and steel sash construction, and has the most modern equipment.

**The Combustion Engineering Corporation** announces that James Cleary, formerly manager of their Philadelphia office, will assume management of the Detroit and Cleveland territories with headquarters in Detroit. Frank Henderson will continue in charge of the Cleveland office. Joseph Lappin, formerly in charge of the Detroit office, has been assigned to New York for special work. The Detroit office has been removed from the Penobscot Building to the Book Building, 1227 Washington Boulevard.

## Traffic

### Approve New Rates in New York

The Public Service Commission of New York has approved joint rates on coke, coke breeze, coke dust and coke screenings, the direct products of coal, in carloads on the Delaware, Lackawanna and Western R.R. from Harriet to various stations on the Buffalo, Rochester & Pittsburgh; of the Lehigh Valley from Harriet to various stations on the Buffalo, Rochester & Pittsburgh and the Pennsylvania R.R.; of the New York Central (east) from Harriet to various stations on the Buffalo, Rochester & Pittsburgh and Pennsylvania R.R., effective Dec. 7 to 9, 1924. No joint rates have hitherto been in effect.

Approval also has been given to new rates on the same commodities on the New York Central (West) from Buffalo and East Buffalo to Derby of \$1.13 per net ton (reduction, 13c.); to Portland, \$1.39 (reduction 12c.); to Van Buren, \$1.39 (increase, 13c.), and to Westfield, \$1.39 (reduction, 12c.), effective Dec. 10, and to reduced rates by the New York, Chicago & St. Louis R.R. on the same products from Buffalo and Buffalo Junction to various stations west, effective Dec. 10.

### Hearing to Consider Proposal to Advance Hard-Coal Rates

The Coal and Coke Committee, Trunk Line Territory, announces a Public Hearing, 11 a.m., Dec. 4, at 143 Liberty Street, New York, on a carriers' proposal to advance rates on anthracite, buckwheat and smaller sizes, from Taylor, the Scranton-Taylor Coal Co.'s washery at Pyne and Jermyon No. 1 collieries to stations on the Delaware, Lackawanna & Western R.R., Forty-Fort, Pa., to Plymouth, Pa., inclusive. The present rate is 88c. per gross ton and the proposed rate is \$1.01 per gross ton. The reason for the proposal is to remove violation of the long and short-haul clause of the Pennsylvania State Constitution.

### Indiana Coal Fields Fear Rate Discrimination

Coal producing fields of the Wabash valley are vitally interested in the Interstate Commerce Commission's hearing on coal freight rates from Ohio and West Virginia to Indiana points, set for Nov. 28 at Indianapolis. If further decreases are granted in rates from Ohio and West Virginia, as petitioned by the Indiana State Chamber of Commerce, without a corresponding adjustment between Indiana points and from the Indiana fields to Michigan and other points north and west it is felt that the Indiana producers will suffer.

The Terre Haute Chamber of Commerce co-operated with the State Chamber in the rate equalization fight which resulted in the present tariffs, making it possible for Indiana to compete more easily with Ohio and West Virginia. In the hearing set for Nov. 28 the Terre Haute Chamber of Com-

merce will appear to protect the interests of the Indiana producers and miners, but the petition of the state chamber asks for a further reduction of rates from the Ohio and West Virginia fields to Indiana points.

## Association Activities

"Pioneer Development of the Coal Mining Industry in Northern Cambria County" was the subject of an interesting address delivered by James A. McCain, banker and former coal operator, at the seventh semi-annual meeting of the Mining Institute of the Fifteenth Bituminous District of Pennsylvania, held in Barnesboro, Pa., on Nov. 1. Other speakers at the meeting were W. F. Dill, of Barnesboro; W. G. Duncan, of Connellsville; J. F. MacWilliams, of Cresson; J. I. Thomas, of Johnstown; E. A. Holbrook, dean of State College; Joseph Williams, of Altoona; J. T. Ryan, of Pittsburgh; N. D. Hubble, of State College, and Prof. William R. Chedsey, of State College.

## Obituary

George F. Cant, of Huntingdon, Pa., who was an operator of coal mines in Cambria County, died suddenly at his home in Huntingdon, Nov. 2. For the last six months Mr. Cant's heart had been affected, but his death was sudden. He operated the Warren Collieries, at Nanty Glo, Pa., for the past six years. Prior to that he had been engaged in operating a gold mine in North Carolina, and bituminous coal mines in the Broad Top section, Bedford County, Pa.

Henry J. Burton, Sr., 60, widely known mining engineer and formerly a mine examiner, died at his home in Pana, Ill., Nov. 3, after having been in bad health for five years. He leaves a widow and two children.

W. H. Lake, a leading business man of Pictou, Ont., died suddenly Nov. 2, aged 82 years. He had been engaged in the coal trade for many years until his retirement a few months ago. He leaves a wife and one daughter.

W. Hubert Young, age 43, a prominent coal man of Oneonta, Ala., died Nov. 12 in a local infirmary after a short illness.

## Coming Meetings

Lehigh Valley Section of American Institute of Electrical Engineers. Annual meeting, evening of Nov. 21, Schuylkill Country Club, Pottsville, Pa. Member Executive Committee, W. H. Lesser, Frackville, Pa.

Illinois Mining Institute. Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

National Exposition of Power and Mechanical Engineering. Annual exposition, Dec. 1-6, Grand Central Palace, New York City. C. F. Roth, Grand Central Palace, New York City.

American Society of Mechanical Engineers. Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

West Virginia Coal Mining Institute. Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Coal Mining Institute of America. Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

American Institute of Mining and Metallurgical Engineers. Annual meeting, Feb. 16-19, 1925, 29 West 39th St., New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

## New Equipment

### These Air-Motor Hoists Are Fit for Many Jobs

The new line of air-motor hoists recently developed by the Ingersoll-Rand Co., 11 Broadway, New York, contain many novel and distinctive features and in addition possess all the essential features which two decades of familiarity with the field has shown the manufacturers to be necessary.

The new hoists are suited for a wide

Air-Driven Shop Hoist

These units are ruggedly built, if greatly overloaded they merely balk, but can be started up again when the load is reduced without any serious effects.

range of service and are used in all manner of industries where rapid and economical lifting and handling of loads is desired.

The 500-lb. capacity hoist was recently put on the market but now the company has developed four larger sizes of similar design so that the same type of hoist is available for heavier work. The four new sizes embody all the features of the smaller hoist except for such variations as in the gearing on the two heaviest sizes, etc.

The outstanding characteristics of the new hoists are briefly as follows: Compactness of design, resulting in low headroom required; relatively light weight; automatic brake which positively holds the load under all circumstances—even if the air supply should become disconnected or fail; and a

graduated throttle which permits a very close regulation of both the lifting and the lowering speeds.

A balanced three-cylinder air-motor is used which operates in either direction and without vibration at any speed or load and within the rated capacity of the machine. The new motor retains all of the best features which have established their worth by long service, and furthermore embodies new features which add to its economy and durability. Some of the advantages of this motor are its freedom from vibration, the ready manner in which it can be throttled down slowly at all loads and its remarkable absence of lubricating troubles, even when subjected to considerable neglect and abuse.

It should therefore be noted that these hoists are entirely distinct from direct acting cylinder hoists and lifts. The latter consist essentially of only the plunger and a case. The air hoists, on the other hand, are equipped with a high-powered and efficient air motor which is geared through a mechanical train to a hoisting drum.

The throttle graduation on the new hoists is very fine and this ensures instant and complete control of the hoist at any speed and contributes to the excellent operating performance. A safety stop lever is provided which closes the throttle and stops the motor whenever the load by chance is raised to the top of the hoist lift.

The automatic brake is a new and

valuable feature as it holds the load at any desired position for any length of time, regardless of air pressure. The brake consists of a disc attached to the motor shaft, and of a brake plunger with a friction face, which is held in contact with the disc by springs whenever the hoist is not operating, i.e., whenever the air supply to the motor is cut off either by throttling or otherwise. It is entirely automatic in its action and requires no attention from the operator.

The lubrication of all parts has been thoroughly provided for. The motor and gears are both inclosed. The motor operates in a bath of oil and the gears turn in a heavy grease. Oil passages lead to all bearings.

Ball bearings or bronze bushings are provided at all points where experience has indicated they will add to the efficiency or life of the hoist.

These hoists are capable of standing up remarkably well under hard service. If a hoist be overloaded it is only necessary to remove the overload, after which the hoist will start up and work again as well as ever.

A roller bearing mono-rail trolley or top hook mounting can be provided as desired. The trolley mounting reduces considerably the head room necessary for installing. Further, because of its rigidity, which enables an operator easily to start a loaded hoist along a runway, it proves more satisfactory than hooking into a separate trolley unit.

## Watt-hour Meter Supplied with Power-Factor Curve

Increasing interest in volt-ampere measurements and power-factor analysis under operating conditions led to

View with Cover Removed

Independent element construction affords a means for determining the power-factor of a load, simplifies meter calibration, and reduces repair part stocks.

the development of a new type poly-phase watt-hour meter by the Sanyo Electric Co. of Springfield, Ill.

The meter has two completely independent single-phase elements, placed side by side instead of one above the other, and geared to a differential train that totalizes on a single register the algebraic sum of the energy measurements of the two elements.

By noting the number of revolutions made by each of the two disks during a definite interval of time the power-factor readily can be determined from

Power-Factor Chart Mounted on Case

Assume one element makes 4 revolutions while the other makes 10. Find the ratio between these (0.4) on the base line, move upward to intersection with the curve then to the left and the reading shows a power factor of 0.8 or 80 per cent.

for calibrating the familiar type of polyphase meter.

In this new meter all constructional details except the base, case and register are identically the same as in the single-phase meters which the company has been making for a number of years.

## Heat Exchanger Is Compact And Leakproof

A novel design of heat exchanger for the efficient interchange of heat between liquids is shown in the accompanying illustration.

By using two short exchangers connected by a flexible bend and shell cover, a compact, rugged, readily portable, and easily installed unit is obtained, approximately half the length of a single unit designed for equivalent duty. This twin arrangement divides the tubes and shell expansion parts into two units, and makes inspection and cleaning much easier.

In this exchanger, the cooling liquid and the fluid to be heated flow in opposite directions in order to provide the most efficient exchange of heat. Two styles of baffles are used to guide the liquid around the tubes, the selection depending upon the loss of pressure in the shell that conditions will permit. To simplify piping all connections are at the same end. Floating heads and head covers eliminate the strain on tube heads and prevent danger of cracked tube plates. This heat exchanger is manufactured by Griscom-Russell Co., 90 West St., New York.

a graph mounted near the name plate on the box cover. All that is necessary is to divide the number of revolutions made by the slower moving disk by the number of revolutions made by the other disk. The graph or curve then can be used to convert this quotient into power-factor.

### METER ELEMENTS ARE INDEPENDENT

Electrically and mechanically the two meter elements are entirely independent and each may be calibrated exactly like a single-phase meter and adjusted without reference to the other. It is claimed that this requires less time and equipment than ordinarily necessary.

### Twin-Unit Heat Exchanger Easily Takes Stresses

High working pressures can be used because of the design of the parts; all stresses are counterbalanced. Baffles cause the liquids to pass in opposite directions and efficiently transfer heat.

## A Post-Graduate Course

PHYSICIANS and surgeons who desire to progress take supplementary courses to keep up with the times. In the coal industry, the technical press and in a minor degree travel from mine to mine, even from country to country, is relied on for a similar result. Many find a further opportunity in attending institutes. The Coal Mining Institute of America holds its post-graduate course this coming week. Let us hope it will be well attended. It is a clinic to which we go not as patients but as doctors of mining engineering. He who would advance cannot safely overlook such an opportunity. It is a waste of valuable time to stay at home when industrial experiences are being exchanged.

## Twenty-five Years Without a Fatality

VIEW it as you please, the Gay record for safety recorded in this issue is remarkable. A quarter century without a fatality yet producing an average of 100,000 tons a year! Of course, as some will say, the roof is good, but it wouldn't be safe without careful watching, and concentrated mining makes such close supervision possible. The roof is only one of the occasions of accident, even though the most important, and the Gay Coal & Coke Co. has avoided accidents from these other causes also. It has also regular and easy grades, and these are in its favor. Still there is no way of belittling the record. It stands as an unusual achievement.

As said, Gay methods of mining make a complete control of operations easy. Strategic points within the workings are connected to each other and to the surface thus affording direct communication between officials. But the men at the mine can claim much of the credit. They have given continuous and hearty co-operation. Their steady work and fair treatment have inspired loyalty.

More than ordinary care has been taken to choose the best men to occupy responsible positions. No man is allowed to run a locomotive unless he has first served time as a trip rider, and he must be qualified otherwise. Only motormen on regular duty are allowed to operate locomotives. The promiscuous running of locomotives during the night shift by any man who happens to be on the job is not permitted. Only 250 volts is used on the trolley lines. The timbering is done by company men and done systematically and when needed. That is a detail that makes for safety.

Equipment of all kinds is kept in excellent repair. Locomotives and other rolling stock as well as all portable machines are frequently inspected, and any defects found are corrected on off-shifts. Mine track is kept in shape religiously. Wiring and other miscellaneous details are maintained in condition

meticulously. Here good engineering practice has counted. It has not increased costs; it has diminished them and decreased accident.

It would be difficult to find such a chronicle if you searched the records of operations under the blue sky where darkness does not interpose its dangers. The Gay mine affords a record for all the world.

## Are Mines So Unhealthful?

WITH a number of useful illustrations Mr. Harrington in this issue vindicates his statement that our mines are not as sanitary and healthful as they well might be. Before accepting his statement, however, we would like to know somewhat more clearly where his facts were obtained. In the West are a number of so-called "lungers" who have gone to a dry climate to enable their weakened organs of respiration to recover from disease. If these men are miners or enter the mines on reaching the West it would not be surprising if they made a bad showing.

His attack on the use made of statistics, American and British, especially British, is not without justification. It is true that miners whose physique is below the average leave the mines and so increase the mortality rate of non-miners. Those who have drawn conclusions from data attainable are mostly men who have no opportunity to make original inquiries to ascertain the life history of several thousand men and draw from these data a more definite understanding of actual conditions. And indeed if they should do so their inquiries would be of only partial value, for local conditions would not afford a conspectus of the whole industry.

The coal dust in one region might be worse than in another as to density, fineness and sharpness. So let us not with Mr. Harrington term the men "sheep like" who draw such conclusions and make such statements. They merely do their best to obtain conclusions from inadequate statistics. Alas that statistics are so inadequate! After all, Mr. Harrington has drawn some conclusions from imperfect figures. How does he know, we would ask, that the farmers and shopkeepers in the cases he instances were formerly miners? How does he know that the miners whom he found suffering from tuberculosis were free of it when they entered the mines? It may be so, but we doubt if he has statistics to show it.

The industry, we feel certain will please Mr. Harrington in the zeal with which it will wet down the coal. But his assurance that the West has led the way in this regard would be disputed by Milton H. Fies, vice-president in charge of the de Bardeleben Coal Co., of Alabama, who gives credit to that state for first wetting down cutter bars. Alabama has gone ahead energetically in this direction.

It is certain that room faces should be better venti-

lated for safety from gas as well as a defense against dust, oxygen depletion, carbon monoxide, nitrous oxides, and hydric sulphide fumes and as a means of stimulating production. Consequently Mr. Harrington has done a service in advocating it.

---

### We Could Do That Ourselves

MANY backward nations have been taken in tow by those that were more progressive and these parental governments have introduced measures resulting in the increased comfort and greater well-being of those whose freedom and self-control were thus restricted. In almost every case the subject nation arrives at a point when it asks, Could not we by adopting the methods of the nation which rules us attain the results that it has achieved? Could we not take back our freedom and run our own affairs? Could not we ourselves do what they are doing for us?

The coal industry is in a like position. For many years it was backward in solving its power problems. Antiquated equipment was all the mines had. They had to burn their good coal to raise steam. They used steam hoists. They wasted power. They had an ill-regulated load. The night duty was almost nil; the day duty was heavy. Bad water levied continuous toll. The mechanical and electrical engineers—where there were any—complained bitterly, pointing out that if such inferior equipment was provided no good results could be obtained, but they were not heard.

The rulers of the mines were mining men; they had little interest in mechanical and electrical details. They spurned advice. They wanted power; and the engineers, who were required to provide it, must supply it cheaply and give it when and where it was needed. Why, the electrical engineers were asked, should they try to regulate the mine in the interest of their own inefficiency? Why demand that pumping be made a night duty? Why talk of smoothing out peaks? Why call for electric hoists when steam would do the work?

This went on till the companies gave up their suzerainty to the public utilities, which promptly put the mines under a regimentation which suited their own advantage. The companies, to save money, began to smooth out their load curves. They watched the meters that the power corporations had installed for the purpose of keeping jealous guard of the coal companies' misdoings. Thus the companies reformed and now they are asking, as all liegemen ultimately do, Why could we not do that ourselves? Why do we have to listen to these outsiders? If we had but heeded the advice of our own mechanical and electrical experts we would be producing our own power today.

So perhaps operators will get down to the business of manufacturing their own power, making mechanical and electrical matters—or electrical and mechanical matters, at your pleasure—their own especial interest. The consolidations of coal companies are making possible large power plants with the economies that go with them, and perhaps we shall herald another era when the power consumed at the mines will in general be produced there. The control of the power companies, however, will have been good for the coal industry. In some cases the electrical or mechanical engineer will be placed in charge instead of in duress. We are waiting to find out if that is what is going to happen. But while there is a doubt, perhaps it would be well for the mining engineer to brush up on his electricity.

He might find himself laid on the shelf otherwise. In any event he should know enough to handle economically the power that his company is purchasing.

E. J. Gealy's story of Illinois shows that in that state the coal companies have not laid down supinely and put into the hands of others an important part of a business that they should have undertaken themselves. It may be that in Illinois engineers have seen their duty more clearly than elsewhere and sold to the operator the value of installing proper equipment for power generation and the need for regulating the use of power so as not to overload plant or transmission lines.

---

### Better than Rock Dust?

WHEN Professor Wheeler was here he assured us that Great Britain was looking for something better than rock dust, but was so well satisfied with it despite its faults that it was prescribed in that country for all dry mines and would probably be required even in those that were naturally wet. Since that time Great Britain has required the use of inert dust in all mines producing bituminous coal.

The only substitutes proposed are salts, soaps and oil. None of these are without their objections, and for the present the dictum still seems to favor incombustible dusts. Every cure will lose its efficiency if not applied frequently, provided more coal dust is deposited, and probably all the substitutes have the disadvantage that in time even without deposition of dust they will lose part or all their efficacy.

So it would seem wise to adopt the method to hand promptly. Certainly no mine will do well to solve the problem by doing nothing. Winter approaches with its menace, and the mine which has made provision of no kind or has provided only for the moistening of the air current will have shown the worst of judgment as a single explosion will abundantly prove.

Many suggestions can be made as to the varying recommendations of experts, but cast your mind backward. The electrical engineers years ago advocated direct-current generators. These machines served that generation well. They justified in a degree the judgment of the electrical engineers; but eventually alternating currents with substations and motor-generator sets and rotary converters took the place of the direct-current generator. The pump men advocated reciprocating pumps and they still have their part to play, but after a while the centrifugal pump proved best for large volumes of water and reasonably high lifts especially for discontinuous service, and the mining public recognized their advantages; thus many have been installed.

If we wait for the final pumping solution our mines will be drowned out. If we delay for the last word in electrical practice our haulage problem will bankrupt us. If we linger till the final judgment is rendered on immunization of our mines from dust explosions our heading and mine faces may be strewn with the victims of our dilatoriness. Consequently it is well to prepare at once to rock dust our mines lest retribution, dire retribution, follow. Who will dare defend himself if his mine blows up, and he is found still waiting for the decision on the best practice that the year 1950 or 2000 may make? We have our 1924 problems. Let us use the only available decision, that of 1924 and preceding years. That is not to say that experts should not study the value and possibilities of substitutes and give the problem the benefit of their careful thought.

*Gobbing a Parting by Machinery*

## With Slabbing System and One Machine Loader Gay Handles 250 Tons of Coal in 8 Hours

Wide Pillars Between Room Pairs Slabbed on Both Sides Concurrently—Mechanical Loader Increases Output per Face Employee 40 Per Cent—Parting from Eight to Twenty Inches Thick Removed by Arcwall Machine

BY ALPHONSE F. BROSKY  
Assistant Editor, *Coal Age*,  
Pittsburgh, Pa.

ON THIS DAY of national thanksgiving the Gay Coal & Coke Co., of Logan County, West Virginia, celebrates its twentieth anniversary as a coal producer. Through this score of years it has mined over 2,500,000 tons of coal, without a single fatal accident.

The State Department of Mines of West Virginia cites this record with justifiable pride. By merit of it the company enjoys the lowest compensation rate that the state law allows. Such a record is well worthy of note, especially as it comes as the result largely of a carefully planned method of operation.

Shortly after the Gay mine was opened, or to be exact, in January of 1905, the management began a series of experiments in mining methods, all of which were based on the principle of longwall operation. These tests developed new safety measures and established the conviction that thick beds of coal can be operated successfully by longwall, even when found under fairly heavy cover. Incidentally, they disclosed the fact that coal can be produced in some beds by a modified longwall system at a lower cost than by room-and-pillar methods, even though the roof neither bends nor breaks freely. Evidence of lower cost is found in continuity of operation, for in the score of years that this mine has been worked it never has been shut down, either by reason of a strike or from any other cause. In weighing this fact, also, it must be remembered that the mines of Logan County have not always enjoyed the economic advantages which they now possess.

At first an attempt was made to produce coal from a continuously retreating longwall face. This system, however, failed chiefly because the roof could not be controlled. From this experience the single-room system

was devised, in which a modification of longwall mining was attained by widening the rooms. Many of the details of this system have undergone alterations, and the plan now employed is the result.

### SPECIFIC CONDITIONS FIX ROOM PROPORTIONS

Up until 1915 rooms were driven 10 to 12 ft. wide and 285 to 300 ft. long on 100- to 120-ft. centers. These dimensions were not arbitrary, but specific conditions dictated their exact proportions. The rooms were then mined, one at a time, either advancing or retreating, to a width of 80 to 90 ft. This was done by slabbing the blocks between rooms in longwall fashion, leaving pillars up to 30 ft. wide for roof support. No attempt was made to recover these narrow pillars, and their presence in the abandoned section assured the success of the system, because directly above the coal lies a 30-ft. bed of strong sandy slate which caves with difficulty even in wide spans.

In driving these single rooms sufficient air could not be carried to the faces, consequently crosscuts were driven between adjoining rooms after these had progressed for half their length. Brattices were also used to facilitate ventilation. The inadequacy of the ventilating system and the expense of driving rooms in this manner led to the adoption of the double-room system.

No. 1 main heading (see Fig. 5) from which the old section of the mine was developed, consists of two entries, whereas the No. 2 main, which serves the sections now being worked, has three entries. These are protected by 100-ft. pillars and driven in a southwesterly direction up the pitch, the grade of which is  $1\frac{1}{2}$  per cent. Butt entries are accordingly driven level, except

for local dips in the coal measure. This arrangement gives grades favoring the loaded cars.

Where the coal is clean, main and butt entries are driven 15 ft. wide with 40-ft. chain pillars between them. In the sections of the mine now being worked most vigorously, a soft-shale parting, sometimes as much as 20 in. thick, divides the bed into two benches. This makes it necessary to drive the headings 18 ft. wide instead of 15 ft., the additional width being needed for the storage of the refuse, none of which is taken out of the mine. In like manner the thickness of this shale band governs the initial width of the rooms.

In the double-room system, the butt entries are driven at such intervals as will leave a panel 350 ft. wide between them. Pairs of rooms are then driven on 185-ft. centers so as to divide the panel into blocks 135 ft. wide and 350 ft. long. Each room of a pair is driven 15 to 18 ft. wide on 35-ft. centers. These dimensions are shown in Fig. 1, which indicates the plan by which the double-room system is operated.

Driving the rooms in pairs instead of singly and dividing the panels between the butt entries into blocks serves two purposes. Not only does it facilitate ventilation in this narrow work, but it also allows the intervening blocks to be mined from both sides simultaneously. This is accomplished by successive slab cuts advanced toward each other and toward the center line of a block, as shown in Fig. 1.

#### CHAIN PILLARS AND SLABBED BLOCKS LEFT IN

In order to protect the butt-entry haulage roads, especially when the system is worked advancing, these slab cuts which average 300 ft. in length are gradually

shortened as they approach the center line of the block. This leaves a somewhat triangular stump which is recovered in retreat.

The percentage of unmined coal left when an area is abandoned depends entirely upon the conditions. Chain pillars between rooms are never recovered. Though an attempt is made to mine out the coal in the blocks between room pairs, as in block 2 of Fig. 1, the roof sometimes shows signs of breaking near either or both of the approaching faces as the pillar between them becomes narrow. In this event the pillar is abandoned as is shown in block 3 of Fig. 1. The average recovery of coal for the entire mine is about 80 per cent, which compares favorably with that attained throughout the Logan field.

Track of 32-in. gage is laid parallel to the face and at a distance from it of 5 ft. If the roof shows no weakness the first row of timbers is placed 15 ft. from the pillar. Under weak roof and during the last few cuts finishing a block, this distance is shortened to 11 ft. The average, therefore, is about 13 ft. This measurement is, of course, the average span of unsupported roof along faces before they are cut. Consequently, depending upon roof conditions, the maximum unsupported span in front of a newly cut face including the depth of the machine cut varies from 17 to 21 ft., giving an average of 19 ft. The arrangement of a face may be seen in block 4 of Fig. 1.

Posts of an average diameter of 8 in. are placed on 10-ft. centers, in rows 6 ft. apart. No attempt is made to recover them; in fact their presence for some distance in the rear of the face retards any subsidence of the roof, and so prevents the coal face from being subjected to squeeze. It should be remembered also that the

Fig. 1—Double-Room System of Modified Longwall Advancing Used in Gay Mine

Rooms are driven in pairs with a 20-ft. pillar between them which is never recovered. It helps to support the roof while the wide pillars on either side are being removed. These pillars are slabbled from opposite sides, successive cuts advancing toward each other. The faces are center cut, and the two benches drilled by machines on the face track. The coal is loaded mechanically.

FIG. 2

**Cutting Face**

A heavy shale parting in the middle of the bed is removed by one, two or three cuts of an arcwall machine operated from a face track. This enables the machine to cut to a uniform depth and move rapidly along the face.

blocks are mined at a rapid rate and that the roof is sound. That is why the posts are capable of serving the purpose described. As a rule, the initial set of the roof is not appreciable. Even though the timbers might be recovered with safety, the procedure would be hampered greatly by the refuse from the cutting machine that is piled between them, the machine making its cuts in the soft-shale parting. When clean coal is mined by this system and the roof will permit, many of the posts can be recovered.

Over fairly long spans the roof is self-supporting to the extent that it will not come down for a long time after the coal has been removed, nevertheless there would be more or less bending of the roof strata immediately above the coal were timbers not employed. This bending or subsidence becomes greatest along a line midway between the center of a block and an adjacent room pillar, as indicated in block 2 of Fig. 1.

As this point of ultimate maximum subsidence is approached by the working face, either the diameter of the posts or their number is gradually increased. Conversely as the working face recedes from this line, either the diameter of the timbers or their number is gradually diminished. This practice is not necessary in mining all blocks, but is followed where the roof in the early stages of block extraction exhibits a tendency to bend. The same reason that dictates this practice also forbids recovery of the timbers and of the narrow room pillars. It is adopted in order to avert or delay the occurrence of a local squeeze.

**ACRE AND A QUARTER STANDS FOR MONTHS**

In one section of this operation a mined-out area having a width of 136 ft. and a length of 400 ft. has been standing for months, without the surrounding coal being apparently affected adversely. The first experiment with a system of retreating longwall on a 300-ft. front, in which the face was mined for a distance of 120 ft. without causing a roof fall, proved that in the use of any modification of this system, under the conditions that exist in the Gay mine, squeezes can be avoided only by leaving pillars at given intervals. Whether the thickness of the cover above the bed is 500 or 1,000 ft., the chain pillar between each pair of rooms serves its purpose with almost equal effectiveness.

Extensive falls of roof, of course, occur in many parts of this mine, although in most instances the lapse of an appreciable interval is required for this action to take place. Such falls give ample warning. The timbers take weight gradually, cracking or brooming as much as 6 in. before they break. Diligence must be exercised in

the supervision of the last few cuts that complete the mining of a block. One of the two approaching faces is abandoned and the track removed. This permits greater concentration of effort along the face being worked and a quicker-withdrawal at the first sign of danger.

**MATCH STICKS GIVE WARNING OF MOVEMENT**

On off shifts during this stage of the work no mine cars or machines are left along a working face, but timbers are set closer and the roof is watched with extreme care. Mud seams in the roof are dangerous, particularly if they occur near the center line of the block being mined. Cracks are observed periodically for any increase in their width or the advance of one side beyond the other. Slight movement between the two sides may be detected by the falling of small sticks, such as match stems that have been inserted in the crack.

It is manifest that a greater concentration of work for a given area can be attained in the double-room system than in the single-room. Aside from increased concentration, however, this method affords greater safety. Inasmuch as each block is mined from both sides, the time of extraction is only one-half that necessary with the single-room system, and the distance that each face must be advanced to complete the mining is correspondingly less. As a result the roof has less time in which to act before the block is mined out, and should it show signs of weighting its leverage is of less magnitude.

The success of this system is dependent entirely upon concentration and quick recovery, together with the leaving of narrow pillars at given intervals to support the roof until 80 per cent of the coal in any particular area has been removed. The advantage of leaving pillars to support the roof while the coal between them is being worked out is most readily discernible in the room-and-pillar system. If, however, these pillars are not recovered in second mining their presence in the goaf, according to the usually accepted theory, tends to create squeezes. This is particularly true if such pillars are not of sufficient size or number to support rigidly the overlying strata throughout a long period of time.

From the observations of mining men over a term of years, it has been proved that the larger the percentage of recovery, the fewer are the squeezes incurred, other conditions being similar. In the Gay mine, squeezes, when they occur, manifest themselves only on the narrow pillars in the abandoned workings and generally do not affect the faces being mined. Thus a squeeze developing in block 3 of Fig. 1 either would be completely stopped by the chain of pillars between blocks 3 and 4, or would be greatly retarded by them.

Although there are several conditions in this mine that might be expected to prevent the success of this system, squeezes on the working face are rare. The rigidity of the 30-ft. bed of sandy shale, as well as that of an indeterminate thickness of other strata above the coal, stubbornly resists the force of gravity which otherwise would cause immediate caving or subsidence as soon as the coal was removed.

Despite their apparent inadequacy, the pillars left at given intervals, appear to counteract the force of gravity which tends to bend or break the roof. After a pillar has been abandoned it is capable of "holding its own" throughout a sufficient period of time to enable the mining front to progress beyond the limits of any danger zone that may be established.

#### SHALE BAND CUT OUT BY MINING MACHINE

Quick recovery is highly important. Apparently, 80 per cent of the coal can be drawn from beneath the roof before it has had time to collapse. Before the collapse comes the seat of mining operations has been far removed and is protected by intervening pillars. Chain pillars 40 ft. wide along the butt entries prevent the abandoned panels from squeezing and prevent the squeeze from crossing into an adjoining panel of solid coal. In course of time the roof comes down, thus relieving the pressure and stopping the squeeze.

The clean coal in the Cedar Grove bed (locally known as the Island Creek) which is worked in the Gay mine, attains a thickness of 74 in. A band of soft shale, having an average thickness of 8 in., but sometimes thickening to over 20 in., occurs in the middle of this bed, throughout the sections now being worked. In portions of the bed operated prior to 1915 the coal was practically

Fig. 3—Electric Drill Mounted on a Truck

Mining operations in the Gay mine are highly mechanized. The coal face is drilled by an electric machine mounted on a mine-car truck which moves readily from place to place along the face and is always ready for work.

free of partings, consequently undercutting machines could be employed to advantage. At the present time, a Jeffrey arcwall machine with a 7½-ft. cutterbar removes this shale parting.

Depending upon its thickness, one, two or even three cuts are required to remove this band. A kerf is first made in the top of the band and then widened to the thickness of the parting by one or two additional cuts, the arcwall machine traveling on a track, which is kept 5 ft. from the working face. This distance is accurately maintained in order to keep the depth of cut uniform. The track is laid with 20-lb. rails placed on steel ties

spaced on 2-ft. centers. The light weight of this track permits it to be moved over easily by means of bars to each new position as the face advances. However, in order to provide the necessary rigidity and eliminate trouble in keeping the cutterbar in a correct position, 30-lb. rails are recommended.

A machine runner and his helper can make a double 6-ft. cut along a 300-ft. face in 10 hr., or a triple cut in 16 hr. The best record thus far made by this arcwall machine under the conditions existing, is 1,200 lin.ft. of a single 6-ft. cut in 12 hr. Where the soft-slate band is thicker than the width of one cut and less than two, the second cut is made by traversing the cutting machine.

Four men are necessary to dispose of the "shale bug dust" from a double cut. A 4BU-type Joy loader is used to gather the cuttings from the floor at the face, after the cut has been cleaned out. This machine deposits the refuse on a Jeffrey pit-car loader, because the loading machine is not provided with a swinging conveyor and works with its main axis parallel to the face. The pit-car loader thus serves as an auxiliary conveying unit with its conveyor extending at an angle to the track and discharging the bug dust behind the nearest row of props. This arrangement is clearly shown in the head-piece of this article.

One of the four clean-up men operates the loading machine, two handle the pit-car loader, and the fourth scrapes the bug dust out of the cut in advance of the machine and later on follows after it with a hand shovel, gobbing the material that it has missed. If the arcwall machine has to make three cuts to remove the parting, an additional man, making five in all, is required. Gobbing the bug dust from a cut takes from 5 to 8 hr. depending on the thickness of the parting. Cuttings from an 8-in. band on a 300-ft. face can be cleaned up in 5 hr.

#### TRUCK-MOUNTED DRILL SINKS ALL SHOTHOLES

The shotholes are made by an electric drill. This is mounted on a mine-car truck which travels on the face track as illustrated in Fig. 3. One man does all drilling, another loads and shoots the holes. As a rule about thirty-five holes are drilled in the upper bench of a 300-ft. face and an equal number in the lower one. These holes are started 12 in. from the bottom or top, as the case may be. The bottom holes, which are shot first, are charged with 15 in. of FF black powder. The top holes are charged with 11 in. of the same explosive. Both top and bottom benches are fired with electric blasting caps as prescribed by law. A permissible dynamite is employed for pop-shots.

For many years the management of this mine has been highly interested in labor-saving machinery, and its present methods are the outcome of experience gained during this time. A 5BU-type Joy machine is now employed in coal loading. It handles 240 tons or more in 8 hr. on the day shift. It is also being used on the night shift, in which it loads about 180 tons in less than 8 hr. Less coal is mined in the night than on the day shift because an insufficient number of mine cars are then available for loading. On Sept. 13 last, one month after the machine was installed, it loaded 250 tons of coal on the day shift and 230 tons during the night, making a total of 480 tons in 16 hr. Less than three weeks after its installation, it had loaded 245 tons in one shift. During this shift, however, 1½ hr. were lost in protracted waits

for cars, and  $\frac{1}{2}$  hr. was consumed in moving from one face to another. The time losses mentioned do not include brief periods of idleness occasioned by waiting for trips.

The records above cited were made by inexperienced operators under the supervision of a demonstrator. The

Fig. 4—Coal-Loading Machine at Work

This machine soon displayed its ability to perform the duties for which it was intended. Shortly after installation it loaded out 420 tons of coal in 16 hr., from two long slab cuts. The roof over the working places is strong, neither bending nor breaking freely. For this reason a wide span of unsupported roof is permissible.

management is satisfied if it obtains 200 tons per shift from the loading machine. Judging from results thus far obtained, however, as much as 350 tons per shift from one machine under conditions that prevail in this mine is entirely within the realm of possibility. Before this rate of loading can be attained, however, methods of shooting the coal and handling the mine cars must be adapted to the requirements of the loading machine. Eventually these changes will be made, and the loader will then be given a chance to show what it really can do.

A 6-ft. cut on a 300-ft. face in the 5½-ft. Cedar Grove seam where the coal weighs 83½ lb. per cubic foot in the solid, will yield about 400 tons. Subtracting from this, 50 tons of coal which is loaded by hand, leaves 350 tons for the machine, which is approximately equal to its capacity per shift when satisfactory haulage is provided.

As has been previously stated, a distance of 5 ft. is maintained between the track and an unshot longwall face. This distance is restricted by the inability of the roof to sustain its own weight in an unsupported span longer than the normal 19 ft., or the maximum 21 ft. It is also governed by the requirements of the cutting machine, which operates from the track. Because of the close quarters in which the loading machine must work, it occupies a position with its body parallel to the face and the rear conveyor swung over the track, as shown in Fig. 1.

#### MUST MAKE PLACE IN WHICH TO STAND MACHINE

For general purposes this position of the machine is entirely satisfactory, but it requires hand-loading to clear a space at the front end of the coal pile, in which the machine can take its place to begin operation. No doubt it could clear the required space itself by working from a position across the track, but this would cause a loss of time and some confusion. Consequently, about 25 tons of coal are loaded by hand at the front end of the pile.

Three men—a runner and two helpers—comprise the loading-machine crew. Aside from their work on the machine, the helpers trim the coal cars and tram the empties, when a locomotive is not present. They do no

shoveling. The loading machine cleans up the face and breaks down hanging coal quite effectively. Hand-loaders shovel the coal missed by the loading machine and with their hand picks straighten irregularities along the face. This clean-up yields about 25 tons. The machine crew is paid by the day, and the hand-loaders work by the ton.

Details of the track arrangement are shown in Fig. 1. Straight rails are inserted between curves in the rooms, and short lengths are added to adjust the track whenever it is advanced toward the face. A short length of straight track extends beyond the curve into the aircourse on the inby end of the rooms. This affords storage for several cars in the clear of the loading machine when the latter is working at that end of the room.

A 6-ton reel locomotive is kept in constant attendance on the loading machine. This backs a trip of fifteen cars into a room; five of which on the inby end are cut loose, the locomotive remaining with the other ten while they are being loaded. While the locomotive changes trips the five cars detached from the trip are trammed by the helpers to the loading machine. In all trips other than the first one, the locomotive pulls fifteen loaded cars at a time.

#### LOOP-HAULAGE METHODS MIGHT INCREASE OUTPUT

Although the haulage facilities in this double-room system are vastly superior to those afforded the loading machine in the room-and-pillar method of working, some improvements might be made. In the single-room system of modified longwall mining, as previously used, mine cars moved in a continuous circuit from one butt entry, through the rooms, to the other flanking butt entry. This track arrangement was discarded, however, when the double-room system was adopted. Its application to the present system of mining should increase the output of the loading machine.

Several other changes in the operation of this mine might be introduced with possible advantage. A system of rope haulage that would relieve the locomotive from spotting cars under the loading-machine conveyor might possibly be adopted, but the sharp changes of direction of the track in the room necessary to follow around the entry stumps would interfere with the adoption of any such plan. Any equipment of this kind, however, would necessarily require sufficient power to move a trip of fifteen cars as a unit over grades that in places are against the load.

Room conveyors could not be readily applied to this system under the conditions now existing. This is because of the presence of the shale band in the middle of the bed, which is removed by the arcwall machine. This objection might, however, be obviated by mounting the coal cutter on a caterpillar tractor. In clean coal a longwall machine might be used. In any case, however, the conveyor layout would be complicated by the necessity of getting around the room stumps which are requisite to this system of mining when operated by the advancing method. The room stumps might be eliminated by maintaining a longwall face from butt entry to butt entry, but this change would require that the present system be operated on the retreat.

If a large tonnage were desired from a section, a number of panels between butt entries would be necessary. Room conveyors, aided by a limited length of entry conveyor, would do much to improve transportation in such a layout. They would also render possible

the working of this system in mines having a roof that is weaker than that at this mine, inasmuch as the unsupported span would be shortened to about 12 ft.

As has already been stated, the loading machine does not load out an entire cut in one shift. Each of the other operations at a face, such as cutting, drilling and shooting, is completed in less time than is demanded by the loading machine. As a result, machine-loading in any section must be augmented by hand-loading in order to keep all equipment and crews busy during each shift.

For the first three weeks of its operation, the present

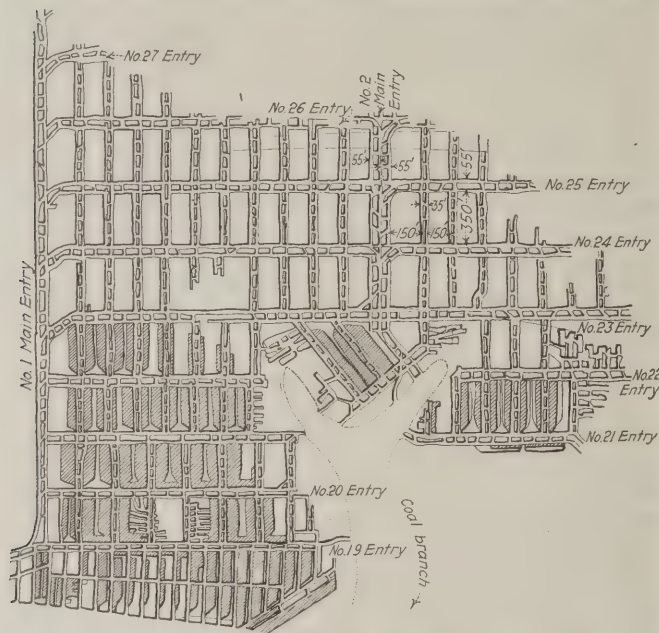

Fig. 5—Map Showing New Section of Gay Mine

Any departure from the system laid out is the result of unusual or unfavorable conditions. Of course, systematic mining is impossible in a tract where the contour lines are irregular. In this mine coal near the outcrop, if recovered at all, is produced by the ordinary room-and-pillar system.

loading machine handled 420 tons in two shifts on full-time days. Needless delays arising from the unfamiliarity of the men with machine operations, occasionally caused the tonnage to fall below this mark. As has been explained, this output is appreciably below a conservative estimate of the machine's capacity in this mine. Nevertheless, the average output per man per shift in the loading-machine section is  $16\frac{1}{2}$  tons, 28 $\frac{1}{2}$  men being required to produce 420 tons of machine-loaded, and 50 tons of hand-loaded coal, making a total of 470 tons in all. The crews and number of men in this section may be listed as follows: Two cutting-machine men, four gobbing-machine men, six loading-machine men (two shifts), one driller, one shotfirer, four haulage men (two shifts), two timber-and-track men, one assistant foreman, and half time for one electrician.

In clean coal, without changes other than the elimination of the four men on the gobbing-machine crew, the output per man per shift in a section of this kind would be 19.2 tons.

Before the introduction of the loading machine, the following men were needed to produce 470 tons of coal when working under similar conditions: Two cutting-machine men, four gobbing-machine men, one driller, one shotfirer, two haulage men, two timber-and-track men, one foreman, one-half time of an electrician, and twenty-six hand-loaders.

A total of 39 $\frac{1}{2}$  men were thus required to produce 470 tons of coal, giving an average of 11.9 tons per man per shift. The twenty-six hand-loaders averaged 18.1 tons per day, which is a comparatively low figure under the conditions existing in this mine. The output per man per day, however, has no direct effect on the cost of mining if loading is done on a tonnage basis. In the Gay mine the best hand-loaders are employed in driving narrow places where a low output per man would seriously affect the cost per ton by requiring more working places for a given development.

The mine here described is an average-size operation, yielding not over 1,000 tons of coal per working day. Less than half this quantity is loaded by one machine, the remainder being loaded by hand. Prior to the installation of this loading machine, the average daily output per man employed, both within the mine and on the surface, was 6 tons. The installation of one coal loader boosted the daily output per man employed at this operation to 7 $\frac{1}{2}$  tons, an increase of 25 per cent.

### Nova Scotia's Bumps Due to Pressure

George S. Rice, chief mining engineer of the U. S. Bureau of Mines, is about to complete a report on "bumps" in Nova Scotia mines, for the government of that province, to whom Mr. Rice's services were lent for the purpose. Though Mr. Rice is not in a position to anticipate his report as to specific recommendations being made to meet the difficult situation which has arisen in Nova Scotia, he points out that "bumps" occur almost inevitably in deep mines where the coal seam has its roof and its floor of strong hard rock. "Bumps" in deep metal mines are known as "rock bursts," and are caused principally by the weight of the overburden.

Before going to Nova Scotia, Mr. Rice personally had inspected similar occurrences in the Crows Nest district of British Columbia, in the mines of south Staffordshire in England, in the mines near Mt. Rainier, in the State of Washington, in certain coal mines in Utah and in some of the Pennsylvania anthracite mines.

Mr. Rice declares that there are local variations in the contributing causes of "bumps." In south Staffordshire, for instance, falls of rock masses in worked-out areas above transmit shock through the rock which at times is sufficiently severe to set up air blasts. In the Crows Nest region rock movements set up quakes which are felt more on the surface than in the mine. The greatest danger comes from the sudden bursting of the ribs along mine passageways, or by the instantaneous upheaval of the floor. The remedy in all cases, Mr. Rice states, is found in maintaining pillars broad enough so as to prevent overloading, and, as mining reaches greater depths, in adopting either longwall methods or hydraulic sand filling. Where the mines are not suited to longwall advancing, retreating longwall methods must be used.

Mr. Rice is much impressed with the conduct of mining in Nova Scotia. The mines are well managed and modernly equipped. The average intelligence among the mine workers is high and greatly simplifies meeting the unusual difficulties which surround the winning of coal in that province. The fact that the Government should call into consultation a mining engineer from another country, is indicative, Mr. Rice states, of the broad policy of securing all possible information which may contribute to the solution of its problem.

*One of the Largest Producers in Illinois*

## How Some Companies Took Time by the Forelock This Summer and Are Now Being Repaid

Weak Market Spurs Mining Men to Heroic Efforts—Big Equipment Makes Possible Large Tonnage When Winter Demands Flood Operators—Success Will Depend on Co-ordination of Machinery with Mine Development

BY EDGAR J. GEALY  
Assistant Editor, *Coal Age*  
New York City

**T**O SAY THAT many of the bituminous-coal executives whose mines were forced to lie idle or work only part time, last summer, were unusually busy during that same period sounds like a paradox. Nevertheless, the statement is true for nearly all the officials were working hard trying to obtain coal orders or devise plans whereby they could mine their product cheaper than their competitors.

As a result of various conferences, all-day sessions and wakeful nights most mine officials had come to realize they were in the throes of a real economic struggle. Some companies which had early appreciated the value of modern mining methods and equipment had placed their orders for labor-saving apparatus and were busy installing the new machinery.

In Chicago, George B. Harrington, president of the Chicago, Wilmington & Franklin Coal Co., was busier than ever directing the finishing touches to Orient No. 2 mine, at West Frankfort, Ill. Here the largest mine hoist in the world was being installed by the Nordberg Manufacturing Co. who built the hoist, and the Westinghouse Electric & Manufacturing Co. who made the two 2,200-hp. motors which drive this double-drum winder.

### POWER BILLS ARE TROUBLESOME

F. H. Manley, vice-president of the O'Gara Coal Co., was busy with power bills and new schedules trying to effect every possible economy. He said, "One of the greatest troubles with purchased power is the big minimum charge a coal company must pay when it is idle or working short time. Purchased power versus mine-generated power is a real problem; sometimes you're

glad you have made a decision one way or the other and yet at times you wish you hadn't decided as you did."

At the Peabody Coal Co. office no one was any busier than Carl Lee, electrical engineer. Important things were turning up so fast that he didn't know whether he would be in Sheridan, Wyo., or still be in Chicago at the end of the week. Mr. Lee was working on problems concerning trolley and feeder voltages. At some of his mines he had found that 55 per cent of the electrical energy used was in the form of direct-current and sometimes 30 per cent of the total electrical energy used in all forms was lost in one manner or another.

### ENGINEERING ECONOMICS IS ESSENTIAL

The solution to this problem, he said, depended upon the economic limit to which the loss may be reduced. Copper feeders cost money to buy, install and maintain, and although he hoped to effect every reasonable economy he did not care to have any of his mines operated as copper producers after the coal had been extracted. Mr. Lee said, "The industry needs to use more engineers, but we must not forget the practical side of engineering." By this he meant what I have often contended. We need business engineers, men who understand the economic and investment side of engineering.

The St. Louis operators were by no means idle. W. Kavanaugh, president of the Southern Coal, Coke & Mining Co., had all his men working on plans to reduce mining costs; in fact, his enthusiasm for coal-loading machines was prompting him to make still further improvements in his equipment to meet the particular

**Fig. 1—Modern Mine Power Plant Operated Like a Public Utility Sells Energy to Nearby Town**

This relatively new plant is capable of taking care of all the mine-load and power requirements of the town of Staunton, Ill. Accurate records are maintained of all the processes involved in the burning of fuel, raising of steam and generation of electrical energy. Power costs are always

available to check the efficiency of the plant against that of other modern stations. The night load and day load of the town are carried at a low cost to consumers. An idle plant during the seasons of reduced coal demand eats into the profit of a coal company, but this plant depends

upon the town load to help pay its carrying charges. A shows the exterior of the well-designed building which houses three 750-kva. turbines and the boiler plant. B shows the automatically-operated stokers in the boiler room that keep the furnaces properly supplied.

conditions in his mines. "Slow periods are the times to spend money," he said, "because that is when nearly everybody else lets his property slip backward."

The Consolidated Coal Co. of St. Louis was just completing a transmission line from its new mine power plant, shown in Figs. 1 and 2, to the town of Staunton, Ill. C. L. Moorman, chief engineer, knows that unusual economies in mine power-plant stations can be realized by raising the all-day load factor by adding loads to off-peak periods. Within a short time the municipally-operated power plant at Staunton is to be abandoned, and power supplied from the coal company's generators. This plan, whereby a mining company creates its own market for coal by converting it into electrical energy, provides for a more continuous operation of the mines and at the same time pays the carrying charges on equipment during periods when it would otherwise be idle.

#### MINE POWER PLANTS CONSPICUOUS

One of the outstanding features of the Illinois coal field is the large number of coal-mine power-generating plants and the many novel ways in which the problem of water supply has been handled. High concrete or brick smoke stacks are evident in nearly all sections. Spray ponds, artificial lakes, reservoirs and streams are

closely adjacent to most of the plants. The Superior Coal Co., at Gillespie, has a plant which gets its water supply from two large ponds. "The water is circulated from one to the other and has plenty of opportunity to cool," said D. D. Wilcox, mining engineer. Donk Bros. Coal Co.'s plant near Edwardsville, where W. J. Clark, general superintendent, has his headquarters, is equipped with a spray pond similar to that of the Consolidated Coal Co. near Staunton.

#### LARGE POWER PLANTS NEAR MINES

Arguments often have been put forward that the coal-mining companies cannot generate a large quantity of power near the coal mines. Indeed, this is somewhat amusing when we consider certain aspects of the question. On the Missouri River near St. Louis where there is plenty of water, stands one of the largest power plants in the world. If a nearby coal company had decided to build and operate such a plant as this it would have had to go no further from its mines to locate its plant where it could get sufficient water than the present power company has to go for its coal. However, if the coal company owned the power plant it would then be in the power-selling business, which after all is something for mine operators to consider. It is not a bad industry with which to be connected.

**Fig. 2—Spray Pond Cools Water Used in Consolidated Coal Co.'s Plant near Staunton, Ill.**

Several parallel pipe lines extend over a large pond adjacent to the power plant. Depending upon the load and weather conditions any number of sprays may be put into service. High-voltage distribution lines connect the plant with the mines and surrounding towns. A shows the spray pond arrangement, and B is a picture of one of the switching towers. Lightning arresters protect all lines and power delays are much less frequent than on some systems which extend over large areas

Fig. 3—Large Smoke Stacks Dot the Countryside

This is one of the latest type of stacks built at coal mines in southern Illinois. As one travels through the region it is an easy matter to locate a coal mine, not because of big breaker structures, as in the anthracite region, but because of the numerous concrete and brick smoke stacks. Almost every mine has a power plant.

One's prejudices are again shocked if one thinks a power plant cannot be located near a coal mine, when one stands at the top of the tippie of the O'Gara Coal Co.'s No. 12 mine near Harrisburg, Ill., as shown in Fig. 7, and can almost touch the smoke stack of the coal company's power plant. Here also the Central Illinois Public Service Co.'s smoke stacks are so close that one questions whether they are not part of the same plant. The water used at the public-utility plant is just as near to the coal company's property as to the power company's station.

The concrete tipples, smoke stacks and fans at this mine recently were described by Ralph Brown, general superintendent. The fans are built to last a long time, as evidenced by the illustration, Fig. 8.

#### FORESIGHT BETTER THAN BACKSIGHT

Someone has said, "In time of peace, prepare for war." There's nothing pleasant in this slogan, but there was in the friendly, industrious spirit around the mines of the J. K. Dering Coal Co., near Eldorado, Ill. All the men, from Lee Haskins, general superintendent to the repair men were happily engaged on some job or another perfecting the mining system, installing new generators, repairing locomotives or merely greasing the hoisting cable. Each man was quite sure that the grade of coal was excellent, the mine well developed and sufficient new machinery had been installed during the summer in preparation of the palmy days of winter coal demand.

At no place was mining activity more intense than at West Frankfort. Electrification was being put into thorough operation at the Old Ben Coal Corporation's No. 9 mine. Here one of the largest single-motor mine hoists in the world was being installed. The electrical and mechanical equipment used with this hoist, shown in Fig. 9, consists of a 43,000-lb. flywheel on a motor-

Fig. 4—Additional Labor-Saving Equipment Necessitated this Addition to a Mine Power Plant

During this summer the J. K. Dering Coal Co., added so much new equipment to the mines that it became necessary to install more generating capacity. All the new work on the boiler plant and generator

room was done this summer; now everything is ready for winter. Inside the mines, feeders and trolley circuits have been extended to the new workings. The illustrations show the additions to the

power-plant building, the new boilers and one of the new generators. Ample space was added to the boiler room for more boilers which will be installed when more generating capacity is necessary.

**Fig. 5—Connecting Link Between the Generators And the Machinery at the Coal Face**

From a new power plant, recently completed at the Donk Bros. Coal Co. mine near Edwardsville, Ill., power is transmitted to other mines owned by the company. High voltages are not uncommon in this mining territory. Large quantities of power are now needed at all modern coal-mining plants because of the increased use of machinery.

generator set equipped with a 1,500-kw. generator and a 1,000-hp. motor which supplies energy to a 2,200-hp. direct-current hoist motor made by the General Electric Co. The hoist itself was made by the Nordberg Manufacturing Co. and is a double-drum of cylindro-conical type, the smaller diameter being 7 ft. and the larger diameter 11 ft. All parts are electrically and

**Fig. 6—Well-Equipped Mine Using Its Own Power**

A neat-looking group of coal-mine buildings all made of concrete greets the visitor's eye when he approaches Thermal Mine No. 4 of the Donk Bros. Coal Co. The smoke stack is a typical marker for coal mines in this region. A central warehouse for all the company's supplies and repair parts is one of the most striking features of this place. Accurate record is kept of all materials which pass through the warehouse, and each month, W. J. Clark, the superintendent, gets a report of the operating cost of each machine used around the mine.

mechanically interlocked through relays and gears. A direct-connected 125-hp. alternating-current motor is provided for inching and repair work. Somewhat earlier in the year the Old Ben Company installed several other large hoists at No. 12 and No. 14 mines near

**Fig. 7—Coal, Water and Power Closely Associated**

The stack in the foreground belongs to the O'Gara Coal Co.'s power plant at No. 12 mine. In the background appears one of the largest public-utility plants in southern Illinois. It answers the question: Can large power plants be located near a coal mine? The picture was taken from the top of the mine tippie.

**Fig. 8—Fan with Duplicate Drive, Always Ready to Do Its Work**

This fan is built in a concrete housing and can be driven from either side. In the brick building in the picture is a steam engine which can be placed in service quickly should something happen to the driver located on the other side of the fan.

Christopher, Ill. The complete units, consisting of the hoist, motor and control were designed by the Allis-Chalmers Manufacturing Co. This giant hoist motor and the \$13,000,000 loan just floated are evidences of the permanence and stability of the Old Ben operations.

There is another point of interest near West Frankfort and that is the Orient No. 2 mine of the Chicago, Wilmington & Franklin Coal Co. Here we see that big two-motor double-drum hoist, illustrated in Fig. 10, of which Mr. Harrington is so justly proud. There are no overhead wires around the mine, all conductors are placed in concrete ducts. The repair shop, steam-generating plant, wash-room, etc., are models which indeed show the handiwork of the Stone & Webster Co. and Allen & Garcia.

Joseph Lewis and John Rodenbush, superintendents at this mine, feel sure that the world's record will be broken when they get the new mine properly developed and the equipment well primed.

Illinois, like many other coal-producing states, is rapidly turning to the use of more and better mining equipment. If there is a danger in this great progressive scheme it probably lies in the improper care and correlation of the machinery now being installed. It is sometimes a relatively easy problem to prove, on paper, the efficiency of a given plan or piece of equipment, but it is a different matter to operate important equipment year in and year out and get best results from it. Paper savings and profits cannot materialize without effort. It is folly to purchase and install expensive apparatus and not provide for proper supervision. Many a good machine has failed to produce the desired results because it has never been kept in tune with the ever-changing mine requirements and conditions.

#### LACK OF CO-ORDINATION MEANS FAILURE

A newly electrified machine or mine may work perfectly the first few months after the manufacturer or consultant has left the job, but before long conditions change, not so much through imperfection in machinery but because of lack of co-ordination of salient parts of the system. There is a need, an urgent necessity, for more engineering skill at the coal mines. Our industry has turned to the use of some of the largest types of machines ever made and has installed the equipment with

Fig. 10—A Large-Sized Power Plant Is Needed to Drive This Two-Motor Hoist

Two 2,200-hp. direct-current hoist motors, one on each end of the drum shaft are required to run this big hoist. Special connections between the generators of the motor-generator set and the hoist motors made it possible to obtain many of the advantages of high voltage and yet not strain the insulation of the windings.

the expectation that it will always fit changing mine requirements.

One cannot conceive of a large generating plant being operated without high-grade supervision, yet many mining companies have enormous electrical connected loads which just run themselves. The performance of machinery at the mines means financial success or failure today, and in many instances it means life or death to the workmen. It is to be hoped that the mining companies will realize the importance of keeping their equipment well balanced.

Fig. 9—Parts of One of the Largest Single-Motor Mine Hoists Ever Built

Electricity and electric equipment has been called upon to perform all manner of service in the coal industry. The installation of this new hoist marks the passing of a big steam-driven hoist which has earned its reward. The day these new parts were being put in position the steam hoist was busy shooting out its exhaust

with a bang, bang, bang which seemed to make you feel it was incensed at its successor the electric motor. Yet with each great puff of steam one could hardly help but realize the tremendous waste of energy continually going on. The photographs show the hoist-motor frame in its shipping case, the large 2,200-hp. direct-current

hoist-motor armature, the 43,000-lb. fly-wheel, used on the motor-generator set, and the hoist drum. Note the two half couplings on the hoist mechanism, one is for the regular hoist motor and the other for an auxiliary alternating-current motor used for shaft repair service when slow speeds are required.

## Machine in Royal Mine Makes Dust and Distributes It

Relies on Ventilation to Carry Dust Over Thousand Feet of Space—Dust Barrier Formed at Each Machine Location

By SAMUEL TESCHER

General Superintendent, The Royal Fuel Co., Denver, Colo.

FOR THE PAST six months the Royal Fuel Co., has been experimenting with rock-dusting equipment in its Royal mine at Aguilar, Colo. It now has in operation at this mine a machine that has been found to be highly economical and efficient in the crushing and distribution of rock dust.

As may be seen in the accompanying illustration it consists of a motor, crusher and fan mounted on one shaft. The whole equipment is placed upon a common bedplate which in turn may be mounted on an ordinary mine-car truck. It thus may be taken into the mine and readily moved from place to place. The advantages of this machine are: (1) Low first cost, (2) mobility, and (3) a decrease in the cost of rock dusting through elimination of the expense of collecting, crushing and sacking the material and then taking it underground.

Inasmuch as many mines are located in coal formations that contain shale it will be perceived that this machine affords a real economy. By its use no dust is lost in crushing, grinding or sacking. Neither is there any danger of the dust becoming caked by moisture before being applied.

The machine now in operation crushes and distributes about 2,000 lb. of shale dust per 8-hr. shift. This is ground so fine that about 80 per cent will pass through a 100-mesh screen. The dust is exhausted from the crusher by means of a fan by which it is simultaneously blown into the air current in the mine. It has been found that the dust not only travels in the air but spreads throughout the mine much as smoke does.

At present this machine is being moved over approximately 1,000 ft. intervals throughout the mine. The

deposition of rock dust is, of course, greatest near the machine and so acts as an effective rock barrier. Thus not only is a 1,000-ft. zone of the mine passages rock dusted but an effective barrier is established.

The fan suction acts in such a way that only the finest rock particles are withdrawn from the crusher. Material that is too large to be effective, automatically remains within this machine until ground down to the desired fineness. Tests conducted on an entry show that at a point 150 ft. from the machine all the dust deposited on the surface of the mine workings will pass a 100-mesh screen.

### DUST CLOUD VISIBLE 7,000 FT. FROM MACHINE

This machine requires only one man for its operation. He feeds the shale into the crusher in approximately 1½-in. pieces. From this point on, the operation is automatic, that is, the machine crushes and blows the dust into the air in one operation. A fine "smoke screen" has actually been observed issuing from the upcast shaft when the machine was located at a point 7,000 ft. from this opening.

By means of this device all the mine workings can be effectively rock-dusted. It has been found that operation of this machine at the mouth of a panel containing fifteen rooms on each entry effectively coated all the roofs, ribs, floors and crosscuts as well as the working faces.

Many mines throughout the country can hardly afford to install an expensive plant for the preparation of rock dust. If, on the other hand, they purchase material already ground, this entails at least the expense of its distribution. In many of these same mines may be found enough shale to answer all purposes if it could be properly pulverized and distributed. Under these conditions such a machine as this would prove highly economical. It can, of course, be moved from place to place throughout the workings and in gaseous operations where it is impractical to station such a machine in the return airway, it may be located in the intake airway and the dust, by means of galvanized iron pipes 6 or 8 in. in diameter, may be conducted through doors or stoppings into the return.

Dust from this machine is distributed in a manner exactly similar to that in which coal dust is deposited. That is, it floats through the air so that particles of coal dust are covered by particles of rock dust of approximately the same size. Tests have demonstrated that this dust travels several hundred feet and finds its way into places that are not directly in the air current.

At the Royal mine the cost of rock dusting has been investigated from all angles. It has been found that this machine makes and distributes rock dust for approximately \$7 less per ton than any other means that has been tried. First cost, as well as maintenance charges, are low and the labor expense after the shale is delivered within the mine consists of the wages of one man only. At the present time the total expense of crushing and applying one ton of shale to the mine surfaces by this method is \$10.50. This includes the cost of mining the shale, hauling it to and into the mine, crushing it, blowing it into the air, moving the machine from place to place, as well as the cost of the electric power consumed in the operation of the machine. All charges have been included in the above figure except the depreciation of the machine itself. Naturally, this item is small. The Hendrie & Bolthoff Mfg. & Supply Co., of Denver, Colo., is agent for this machine.

Grinds Rock and Blows Dust Into the Air

Motor, pulverizer and fan are all mounted on one shaft. The fan withdraws the fine dust from the pulverizer and blows it into the ventilating current. The mine air carries and deposits this inert material exactly as it deposits coal dust. The mine can be effectively rock-dusted by moving the machine through the entries by approximately 1,000-ft. steps. Fine dust may be carried by the air for over a mile.

## Is Coal Industry Blind To Health Hazards Of Mine?

**This Frank Expert Says We, "Sheep-like," Accept Misleading Statistics—Coal Mines "Contribute Far More Than Their Share of Death and Disease"—Rock Dust, Water and Better Ventilation Needed**

BY D. HARRINGTON

Consulting Mining Engineer, Salt Lake City

**C**OAL MINING is pre-eminently no occupation for the physically weak. There are comparatively few underground occupations in our coal mines, except possibly a few provided for pensioners, which do not demand utmost physical strength and endurance. In fact, it is not at all uncommon to hear coal-mine managers state that what is needed in underground workers is that they be "strong in the back and weak in the head," a sentiment with which, however, I am decidedly not in accord.

This demand of the industry for maximum physical fitness is brought about largely by the contracting system of work and tends automatically to eliminate those who in any manner become disabled. While this elimination does not always apply to those partly incapacitated by physical injury (many of whom are in some manner taken care of by the employer), those unfortunates who become weakened by disease are usually forced to leave the mines to go to near-by farms or into some "easy" occupation.

It is largely due to this situation together with the sheep-like acceptance of half-baked statements and misinterpreted statistics, largely of English origin, that there has grown an impression, in fact a positive belief, that coal mining is one of the most healthful of occupations, when as a matter of fact our coal mines contribute far more than their share of disease and of total or partial disability or of death from disease.

Acceptance has been so nearly universal of English and other European statistics as to illness and mortality rates among coal miners that there are available few reliable statistics or tabulated data as to illness and mortality of the coal-miners of the United States. Though there have been a few investigations of these

matters by commissions, the study has usually been superficial and academic. Too often these investigators have based their reports on compilations of available literature largely copied, rather than on information obtained from actual study and observation at the mines. I have had access to some studies, however, which *did*

go into fundamentals, and though I am not able to publish all the data available, some of it will be given in outline.

In a detailed study at one coal-mining locality an effort was made to examine physically about 25 per cent of the men employed, selecting, as far as possible, men who had worked largely or wholly in this particular coal-mining region. It was found that over 30 per cent of those examined had pneumoconiosis, or lung-dust trouble, and practically 30 per cent more were suspected of it or had symptoms of dust trouble. In addition about 90 per cent of those examined had defective teeth.

In a similar study in another coal village in a wholly different region, but also in the United States, it was found that over 35 per cent of those examined had definite lung trouble or pneumoconiosis and an additional 25 per cent had definite symptoms of it. Here again it was stated that a large number of men had trouble with their teeth, though the exact figures were not set forth. In both studies about 95 per cent of those examined were less than fifty years of age.

In the first case cited, there were no mining machines used and the dustiness of the air was due almost wholly to picking down the coal and shoveling it into cars. Face workers were the ones with the most definite lung involvement, and the worst cases had had from nine to fifteen years of experience in working in coal mines. In the second case studied, the coal was undercut by

### WHY DAN SPEAKS OUT

**T**HE AUTHOR of this article has a lot of pointed things to say about the health hazards of coal mining. With customary vigor he hauls off and says them. He is not a doctor and doesn't want anybody to think he claims professional medical standing. However, he has spent a number of the long years of his coal-mining experience studying health as well as safety in coal mines in co-operation with several doctors of the United States Public Health Service and with brother engineers of the Bureau of Mines. In many cases he has been in charge of the investigations that were being made. After having a part in more than one hundred such investigations in both coal and metal mines of 25 states he believes some frank words ought to be spoken to this industry. Therefore he speaks out.

short-wall mining machines and those most definitely affected by dust had averaged twenty years work in coal mines though several had definite lung involvements after two years, the men thus quickly affected being for the most part machine runners. It was found, indeed, that machine cutters were by far the most generally affected, with face loaders next in order.

#### WATER ON CUTTING CHAIN PREVENTS DUST

In one coal-mining district in the West, after the mine-village doctor had advised one after another of the machine runners to leave the mine, the company made a study of the situation and found that the dust irritation was so great that the breathing capacity of the machine runners was much limited, and in numerous instances hemorrhages resulted. To prevent this water is used on the cutting chain. It is said that this efficient remedy for "killing" coal-mine dust was used in the Utah district as early as 1913.

I have at hand a large number of instances in which machine runners and other coal-mine workers have been almost wholly incapacitated by breathing coal dust, having the typical shortness of breath of the metal miner afflicted with silicosis. In several cases hemorrhages resulted; and in a few cases, death. It was this health problem in connection with machine runners that aided materially in the ready acceptance by Utah coal operators of the new safety order now in effect requiring use of water on the cutting chain. Though a few Utah machine runners are indifferent to the new system, none are openly antagonistic and by far the greater number enthusiastically favor this use of the water.

After about eight years of more or less continuous study of the effect of dust on health of miners in mines troubled with the dust of coal, limestone, hematite, silica in various forms, shale, etc., I am convinced that though some dusts are more quickly or more definitely dangerous to the health of underground workers than others, nevertheless any dust found in underground air and breathed by workers in large quantities and finely divided form (say less than 1/2,500 in.) is likely ultimately to be harmful. In case of machine runners cutting dry friable coal, the machine runner in some instances has been "put out of commission" in less than three years.

Dustiness tests of coal-mine air at faces that are being undercut in coal by modern electrically driven shortwall mining machines show that when a spray of water is directed against the ingoing side of the cutter chain, the number of particles of dust in the air is only about one-twentieth of that found when water is not used. The quantity of dust in the air when cutting dry is twenty to thirty times as great as that allowed at working faces in South African gold mines.

It has been determined that, at dry coal faces, picking

and shoveling at even a medium rapid rate makes the air ten to thirty times as dusty as it was when the shift started. Much of this dust is later eliminated from the miner's respiratory organs, but it is pretty well established that a large quantity remains, ultimately clogging them enough to prevent them from performing their functions.

Much nonsense has been written about the coal miner's immunity from respiratory disease and about his being able to resist silicosis when engaging in work in metal mines after having worked previously in coal. It was even proposed a few years ago to introduce coal dust into metal mines having known dangerous dust with the idea of neutralizing the dangerous metal-mine dust by coal dust. In present-day slang, "This is all pure bunk."

In one large coal-mining locality in which a study of adult mortality statistics over a period of several years was made, it was found that, *eliminating mine accidents*, over 25 per cent of the miners who died, had death certificates which read "*tuberculosis*," whereas deaths of non-miners from the same cause in that region were only about 7 per cent and but 16 per cent of the deaths of adult females were from tuberculosis. The death rate of miners, non-miners and adult women from influenza was about equal, being around

7 per cent. However, deaths from pneumonia showed miners over 45 per cent, non-miners a little over 28 per cent and adult women a little over 22 per cent.

In this mortality survey, it was shown that, *eliminating deaths from accidents*, the total deaths from respiratory diseases were: Miners 80 per cent, non-miners 43 per cent and adult women 45 per cent. This would seem to establish the fact that in at least this *one* large coal-mining locality the coal miner is not immune to respiratory disease or even to tuberculosis.

The fallacy of the coal miners' immunity from respiratory disease arises from a number of causes. Where coal miners' mortality records are available they usually show at least 25 to 50 per cent of deaths due to accidents. Hence the percentages of remaining causes of death are from one-fourth to one-half or even two-thirds too low to indicate prevalence of disease. For instance, in one coal-mining region a mortality study showed but 4½ per cent of deaths were caused by tuberculosis; but when the deaths from accidents were eliminated and only deaths from so-called natural causes considered, the tuberculosis death rate jumped to over 16 per cent.

#### FARMERS DRAWN FROM MINES DIE OF PHTHISIS

In a certain coal-mining region it is pointed out that the mortality of miners from tuberculosis has been less than among farmers and storekeepers of the same neighborhood. However the facts are that more farmers and storekeepers of that immediate region died of

#### TWO KINDS OF "SH-H-H!" MEN

PEOPLE in the coal mining business keep altogether too quiet about the dangers of mining to suit Dan Harrington, author of this article. Camp doctors "soft pedal" it, he says, because they are either ignorant from not going down and studying underground conditions or else they are afraid they will be blamed for having a bad camp record. Rock-dust advocates "soft-pedal" it, he says, because they think operators will figure that rock dust is as hard on the men's health as coal dust and therefore rock dusting will get a set-back. As a matter of fact, he holds, rock dust should not be put in places where much of it will be stirred up into suspension. It will serve its purpose elsewhere in the mine if water is used around the working places, and thus will add nothing to the miners' health hazard.

the disease than did farmers and storekeepers in other parts of the same state. It appears then, that partly disabled coal miners who had left the mines, probably diseased, and who had gone into farming and store-keeping near the mines were responsible for the high tuberculosis mortality of that territory and that the comparison between the tuberculosis deaths of miners with outside people of the immediate region is not a fair comparison.

#### DATA ON ACTUAL CONDITIONS SUPPRESSED

Another definite reason why the presence of respiratory disease among coal miners has not been generally known is that for one reason or other those who realize the actual situation suppress the data. Those who are most likely to know about the matter are the doctors in the mine villages. Seldom does a coal-mine doctor write his views for publication, generally because he is too busy, frequently because he doesn't know how to do it and often because he is afraid that his standing with the company will be injured if he gives undue publicity to health danger from dust or from other cause.

The mine doctor knows that the coal operator in most parts of this country would much dislike to be compelled to spend the money necessary to preserve the health of his employees as menaced by the presence of dust, though he ought to do it for the benefit of his own purse, as the dust at the face causes much lost time due to sickness, causes many men to leave coal mines when they should be in the prime of life and certainly is a menace as a possible participant in an explosion.

Oddly enough the "soft pedal" is also placed upon the health danger of coal dust by the enthusiasts who advocate rock dusting to prevent explosions. They feel that if it becomes known or realized that fine coal dust in large quantities in mine air is dangerous to health, those mining companies who might use rock dusting would be afraid to do so, knowing that, if coal dust is dangerous to health, then rock dust or a combination of the two would be worse.

#### ROCK DUSTING IN ENTRIES NOT HARMFUL

As a matter of fact, if the rock dusting is confined to well ventilated places such as main air entries or is placed in unventilated places where there are no men, animals, machinery, etc., to stir the fine rock dust into the air, rock dusting of coal mines is perfectly safe as regards health because there should not be, under such conditions, in the air of such places a sufficiently large quantity of finely divided dust to injure the respiratory organs. However, if rock-dusting methods are introduced at or around the working face where air is usually still and if no water is used, the health hazard will undoubtedly be increased.

The obvious remedy is to rock dust well ventilated entries and non-working dead-air places, but around the working face to use water freely. The best plan is to use a water spray on the cutting chains while cutting, to spray faces, ribs, roof, floor and coal piles several times a day, to sprinkle tops of loaded cars before they leave the face and to wet down at least once daily the region of every room neck or entry face for several hundred feet until the rock-dusted region is met.

If both water and dust are used, the water will aid the rock dusting, the rock dusting will aid the sprinkling and both will promote the health of the

workers and the safety of the mine as well as that of the workers.

Respiratory disease under such names as miner's consumption, anthracosis, pneumoconiosis, tuberculosis, miner's asthma, bronchitis, pneumonia, etc. cause, in my opinion, more deaths and far more misery, lost time and other humanitarian and economic losses among our coal miners than do mine explosions, and it appears that dust inhalation—chiefly of coal dust—is mainly responsible. Except in a few mines and in only one state, Utah, where water must be used at the working face, there is little or no effort being made to combat the menace.

#### HEART TROUBLE AND BAD TEETH COMMON

In a mortality study of a large coal-mining region it was found that if accidental deaths were eliminated, the death rate among coal miners from diseases of the heart was about twice as high as the rate for non-miners and four times the rate for adult women. Apparently the intense effort exerted by the contract underground worker is responsible for this.

As previously mentioned, physical examination of miners (and this applies to both coal and metal mining) indicates that at least three out of four of our mine workers have defective teeth. In view of the fact that later-day medical thought assesses many of our present-day ills against defective teeth, mining com-

**This Line Brattice Is a Doubtful Health Safeguard**

If it were tight enough and not open at the bottom it would be a good conductor of clean air clear up to the working face in this room, thus doing its bit to move out gas and a good deal of dust as fast as they floated into the working atmosphere. If brattices are poor the chances are that men at the faces will breathe enough gas into their lungs to reduce their efficiency even if it does not drive them home to lose time both for themselves and their employers.

panies should ascertain and apply the remedy. The frequency with which defective teeth are found among miners would justify most mining companies in employing the partial or full-time services of a competent dentist to give service to miners at nominal rates or free. State mining departments, state and local health bodies, the Federal Government, should conduct a definite widespread campaign as to care of the teeth.

Carbon monoxide poisoning due generally to breathing fumes from explosives—hence due to poor ventilation or to poor blasting methods—causes some death and much illness among miners with more or less permanent ill effect. In some poorly ventilated mines the air at a considerable number of working faces contains from 0.01 per cent to two, three or possibly four times that quantity of carbon monoxide, and workers have up to as much as 30 per cent of their blood put out of com-

mission at least temporarily by having that quantity of blood saturated with carbon monoxide.

Though some workers at least seem to establish a tolerance so that the carbon monoxide they breathe does not appear to have any particular ill effect on them, others have more or less continuous headache, some have acute nausea, others lose appetite and a more or less general result is chronic irritability. The permanent net result is difficult to ascertain, but certainly some time is lost, and if there were no other ill effect than the irritability (which is easily understood after one has had a carbon-monoxide headache) it is certain that it does not pay any mining company to allow this "disease" in its mine.

Probably the best remedy is to have strong currents of fresh air at all times sweeping over and past places where men work and especially places where explosives have been used or where carbon monoxide may be present from any other cause such as a more or less covered mine fire. Use of black powder and fuse, or of dynamite and fuse, or of coal dust or other flammable tamping material, all tend toward formation of carbon monoxide when blasting. Black powder, dynamite, fuse and combustible tamping material should all be eliminated from coal mines and all shots fired electrically using permissible explosive and inert tamping material. Any coal mine which, in this day, allows any kind of blasting during the working shift certainly shows the minimum regard for the health of its workers or the safety of either mine or miners.

#### NITROGEN COMPOUNDS MAY CAUSE INJURY

There may also be acute poisoning from oxides of nitrogen released by blasting in poorly ventilated places, though this form of poisoning is much more rare than that from carbon monoxide. The immediate remedy for either is withdrawal to fresh air. If the victim is unconscious give artificial respiration and feed oxygen if available, but of course get the patient to the doctor or hospital as soon as possible. To aid in removal of "powder headache," the breathing of pure oxygen is probably the best remedy, though breathing a combination of oxygen and carbon dioxide in proportion of about 9 parts of oxygen to 1 part of carbon dioxide is held by some authorities to be even better than oxygen alone.

In some non-gaseous mines where ventilation can be, and frequently is, neglected, places are occasionally encountered where the oxygen content of the air will not sustain the flame of a safety lamp. Hence it is below 17 per cent though there may be enough oxygen to feed the flame of a "carbide" lamp which requires only 11 per cent. In such places men have more or less continual headache, they lack vitality and upon making any great exertion they begin to puff and are compelled to slow up. Here again is found irritability. If the air temperature is above 80 deg., as found often in metal mines, though more rarely in coal mines, an oxygen reduction of only one-half of one per cent (from 20.9 to 20.4 per cent or less with a correspondingly slight rise in carbon dioxide) will also give essentially the same symptoms as have been just outlined.

I have no definite data available as to whether there are permanent ill effects from long-continued breathing of depleted atmospheres such as those referred to, though old timers who worked many years ago both in Great Britain and in the anthracite and other mines of the United States, say that much of the so-called miner's

asthma came from long-continued breathing of "poor air" in the poorly ventilated mines of those days. There is absolutely no doubt, that these depleted atmospheres make men slow up in their work and cause them at least temporary ill effects such as headache, irritability, lack of appetite, etc.

Though coal miners in the United States usually have ideal underground working temperatures (from 40 to 65 or 70 deg. F.) some coal mines (and many metal mines) have working temperatures in excess of 80 deg. F. Though there is some doubt as to the permanent ill effects of working in temperatures over 80 deg. I am convinced after much underground experimental work and study of the subject, that long-continued work in underground air with temperatures

**Water Helps Reduce Health Hazard**

Mr. Harrington believes in keeping down coal dust at the faces by using a spray on cutterbars but water should be used frequently also to soak down active rooms and entries leading clear back to the end of the rock-dust zone. If this is done the proportion of fine coal dust in suspension ready to injure the respiratory organs of miners will be small indeed.

above 80 deg. F. is likely to reduce vitality, especially where there is much dust present, or high humidity or lack of movement of air or even slight atmospheric impurity.

#### BELOW BLOOD HEAT AIR MOVEMENT HELPS

Though air movement is of great help when temperature is high, excessive velocities (say over 200 to 300 lin.ft. per minute) hurt rather than aid when the air temperature is above the temperature of the blood (about 98½ deg. F.) though velocities up to 100 or more feet per minute give relief when the air temperature is below 98½ deg. and over 80 deg.

One of the most significant features brought out in a study of effect of high underground air temperature was that a certain quantity of work at a definite rate of working which was quite easy (almost child's play) when air temperature was 70 deg. became more difficult with air at 75 deg., still more difficult at 80 deg., thoroughly hard at 85 deg. and utterly impossible of fulfillment at 90 deg.

In practically all cases the air was nearly saturated with moisture, air velocity was slight or practically nil, the work was done on separate days for each temperature and was performed by the same persons, all of whom were in good physical trim and all of whom experienced essentially the same effect. From this it will readily be seen how essential it is that underground working atmospheres be kept below 90 deg. F. even if

no account is taken of the health feature and nothing is considered except efficiency.

A temporary but acute and at times financially costly disease is found in some wet coal mines where small quantities of hydrogen sulphide issue and attack the eyes of workers. The men's eyes become blood-shot, and get to be so painful that they are forced to spend days, sometimes weeks, in a dark room, and in addition their eyes must be treated by the doctor. The disease is called locally "pink eye" and apparently is not permanently harmful, and fortunately, too, the condition in the mine which leads up to it, is usually temporary as the gas (hydrogen sulphide) disappears after the affected part of the mine is left open for a limited time, also the area affected is generally not large.

While it is claimed that hookworm is prevalent in some of the coal mines in the South, I am not familiar with the situation; however, the almost universal lack of provision in coal mines for removal of human filth, gives the hookworm maximum opportunity to spread provided other conditions such as temperature, humidity, etc. are favorable.

#### COAL-MINE DOCTORS ARE INEFFICIENT

I have had an opportunity to become acquainted with a large number of coal-mine doctors and in general they appear to be, in slang terms, "poor fish" though this is not universal. Only two of these mine doctors that I have met have made it a practice to go underground to see under what conditions those entrusted to their care do their work; as a consequence the coal-mine doctors really know little or nothing about underground conditions, and hence cannot aid in the improving of underground health.

Though a few coal-mine doctors help the Bureau of Mines safety car men in their training of underground employees in first-aid methods, many of them handicap the first-aid instructor because they think he is trying to do doctor's work or seeking to train the employees to do it.

Only rarely does the coal-mine doctor take any definite intelligent action for better mine-village hygiene such as construction or maintenance of sanitary latrines, or the filtering or purifying or safeguarding of the water system, or the giving of health or sanitation lectures or talks. Very few coal-mine doctors endeavor to obtain for the miners washhouse facilities, or insist on their proper maintenance, where they are available. And but few physicians in mining villages know how to treat a man who has been gassed underground.

On one occasion where a number of men were brought out of a coal mine unconscious from coal-mine explosion fumes, a galaxy of coal-mine doctors, assembled from the surrounding country, were helpless as babes as to the proper measures to be taken, and if it hadn't been for intervention of a rank outsider, who did know what to do, several of the gassed men undoubtedly would have died.

It would appear that one of the functions of the coal-mine doctor should be that of preventive hygiene; at any rate he should, at least occasionally, go underground and ascertain how or under what surroundings his patients or prospective patients work. In fact, it would appear that coal-mine doctors should have some more helpful functions than doling out a few pills or setting an occasional broken bone.

One of the most essential factors toward making our coal mines healthful is the consistent periodic physical

examination of all employees. If upon being employed, physical examination were made, the applicants proper sphere of work could be determined with some degree of certainty instead of "going it blind" as is now done. Examination semi-annually or annually would check up the physical condition of each individual, so that steps could be taken in time to help correct defects in individuals as well as to locate underlying causes of trouble.

While I emphatically dissent from the often-repeated statements that coal mining is one of the most healthful of occupations, on the other hand, there is no good reason why it should not be made so. And if by the use of water, precautions are taken against making dust at the face, this can be done readily. If the spreading of dust is checked by the use of tight cars, by sprinkling on the top of loaded cars, and by the removal or quick dilution by good ventilation of such dust as will inevitably be made, the danger from respiratory disease will be practically removed. Modern up-to-date blasting methods together with good ventilation will prevent diseases from gases and high temperatures. In fact coal mines can practically eliminate health hazards and make coal mining actually one of the most healthful of occupations.

## Cup-Shaped Cutter Bit Makes Big Power Saving

Eastern Kentucky Company Now Realizes the Inefficiency of Common Bits—New Bit Cuts Four Times as Many Places as Standard Bit

By J. H. EDWARDS

Associate Editor, *Coal Age*  
Huntington, W. Va.

THE North-East Coal Co., of Paintsville, Ky., has developed and is now using a mining-machine bit which is proving of interest to operators and under-cutter manufacturers. The new shape of bit is the idea of E. L. Burton, who is the blacksmith at the No. 1 mine. The service being obtained and the results of electrical test justly lead the North-East company to believe that they have a bit which is superior to any other now available.

A wide, "hollow-ground" cutting face is the distinguishing feature of this bit. The wide face provides cutting clearance and eliminates any wedging effect. The bits are hand-forged from ordinary pick-points which have been purchased from the mining-machine manufacturer. The only special equipment used in

Central Shop of North-East Coal Co.

This shop is well equipped with machine tools for handling the general run-of-mine repair work. Part of the building is reserved for armature winding. The open door at the left leads to an office provided for the shop foreman.

### Actual Power Tests on Machines Equipped with "Burton" and Ordinary Type Bits

Burton.....	No. 1	19	24	9.5	197	54.8	10.8	90
Pick-Point.....	No. 1	17	24	15	198	92.6	18.3	269
Burton.....	No. 3	28	18	18.5	216	51	11	121
Pick-Point.....	No. 3	13	24	13.5	188	88	16.5	284
Pick-Point.....	No. 3	21	18	24	219	48	10.5	200
Pick-Point.....	No. 7	25	18	21.5	215	67	14	205

forming it is a home-made anvil dolly. This is a block of steel the top of which is about 2 in. square. A groove about 1 in. wide and  $\frac{1}{2}$  in. deep is cut through the center, and in the bottom of this groove is a tapered V-shaped projection which, when the bit is placed upon it and hammered, hollows and spreads the face.

An ordinary pair of bit tongs is used, and the cutting angle to be formed is gaged by the angle of the tongs. The cutting face of the bit is ground slightly on an 8-in. emery wheel. Because of the hollowed face the wheel comes in contact with but a small area of metal, this area comprising the point and a narrow strip on each edge.

The bits are resharpened with the same tools and in the same way as they were originally formed from the standard bit, but, of course, the sharpening requires less time. Even the original grinding requires but a fraction of a minute for each bit.

The accompanying table summarizes the results of several electrical tests which the North-East company has made on shortwall machines equipped with the Burton and with the ordinary pick-point bits. Note the exceedingly good showing of 90 and 121 watt-hours per lineal foot of cutting in the two tests of Burton bits as compared to the results 200 to 284 with the ordinary bits. The two first tests, which are set apart at the top of the table were staged as competitive tests and therefore were carefully arranged as to similarity of conditions. The cutting in these two tests was done on the

same entry and on the same side of the entry using the same shortwall machine operated by the same crew. The Burton test was in Room No. 2 and the pick-point test in Room No. 3. The officials of the company feel that these two tests afford a true comparison of the two bits.

The last three tests listed in the table were made at random to determine the power required by the old-type bits under everyday conditions. These bits were hardened by the common "heat and plunge" method, but the points of the Burton bits and of the pick-point bits used in the one competitive test were hardened and then tempered to a straw color. In all cases plain water was used for hardening and tempering. All bits tested were of the ordinary grade of bit steel and were formed to a cutting angle of 35 to 37 deg.

Much care was taken in making the power tests. Re-

One of the Mines at Thealka, Ky.

It was in mine No. 1 that the carefully arranged competitive test was made between the "Burton" and the ordinary pick-point bits.

cording electric meters were not available, therefore simultaneous readings of indicating meters were taken every 30 sec. during the sumping and cutting. The values in the table are averages of these readings, and therefore are of sufficient accuracy to give a fairly true indication of the actual power taken by the machines.

#### NEW BIT INCREASES PLACES CUT

So far no mention has been made of the more practical and perhaps more important advantages of the Burton bit. Mining machines so equipped are now cutting an average of nine and a maximum of nineteen places with one set of bits as compared to an average of two and a maximum of four with the old pick-point bits. When using the old bits it was frequently necessary to "spot" during the first cut and in some cases bits were spotted three times while cutting a single place.

As to the character of cuttings or so called bug dust, no definite tests have been made, however, it is certain that the cuttings are coarser with the Burton bit. This is due to the sharp cutting edge and to the wide cutting face providing the clearance which eliminates any rubbing or wedging effect, thus actually cutting the coal instead of grinding it away.

These recent investigations and tests made by the North-East Coal Company were not confined to the Burton bit. Other types were made and tried, also several of the special arrangements now on the market were put into service but none of these were able to make as favorable a showing as did the new Burton bit.

Showing Details of "Burton" Bit

The one on the left has not been used since being re-formed into the Burton type. That on the right has been used and re-sharpened several times.

## News Of the Industry

### Illinois Miners, Says Fishwick, Are Willing to Give New Methods And Untried Machinery a Chance

Springfield, Ill., Nov. 22.—Miners and operators of Illinois are scanning the horizon for a Moses to lead them out of the darkness of present day economics into the light, Harry Fishwick, of Springfield, vice-president of the Illinois Mine Workers, declared today at the annual meeting of the Illinois Mining Institute.

Other speakers included D. D. Wilcox, operator, of Gillespie, president of the institute; A. J. Moorshead, president of the Madison Coal Corporation; D. J. Parker, safety engineer of the U. S. Bureau of Mines; J. W. Pearce, of the Goodman Mfg. Co., Chicago; Harley Smith, operator, of Chicago, and Martin Bolt, director of the Illinois State Department of Mines and Minerals.

Harry Fishwick's remark regarding the need of a Moses followed the suggestion of Mr. Moses, an Illinois operator, that the Illinois miners should submit to a reduction. "We are all living in a different age than formerly," Mr. Fishwick said. "We are all living better and we don't want to go back. We want to be respectable. I can speak for thirty or forty thousand miners in Illinois who haven't a job. It calls for a Moses to meet that problem. The capacity of Illinois mines is about two hundred million tons. About eighty million tons is consumed in Illinois, but only thirty million of that is Illinois coal."

Mr. Fishwick then gave his pledge on behalf of Illinois miners to stand by their "contract to try any new and untried machinery or systems of mining," but avoided any reference to the possibility of a separate scale. "We stand committed to the word of our contract," Mr. Fishwick said, "and will live up to it even if it takes our hide off. Where my name was placed on a contract, my honor stands with it to do the utmost to carry out every word, without thinking what effect it may have on my political future."

Mr. Fishwick condemned expansion of mining and declared that there should be federal legislation to prevent opening mines where not needed. He said it was the duty of this generation to "preserve for future generations at least their share of anything dug out of the earth for the benefit of all people."

"This generation," he added, "has no right to waste the prodigal resources of this country. I do not think that coal was placed in the earth so the twentieth century might waste it as it

pleased and leave the following generations, like Lazarus, to subsist on crumbs from the rich man's table.

"We should all try to forestall this calamity. To my mind we haven't the right to waste or develop any operation when we can't promise that a market will be ready for the product. We need not go far afield to find something wrong with the industry."

J. W. Pearce, of the Goodman Mfg. Co., which has two loading machines in operation in this state, spoke of the possibilities of mechanical loaders. Mr. Moorshead, president of the Madison Coal Corporation, urged the operators present to visit other mines and copy the cream of the ideas there for their own use. Mr. Parker, of the Bureau of Mines, bespoke a closer co-operation between the State Department of Mines and the federal bureau, that mine accidents might be lessened.

In the election of officers Harvey L. Smith, Chicago operator, was named president; E. G. Lewis, superintendent of the Chicago Sandoval Coal Co., at Sandoval, was named first vice-president; William E. Kidd, Peoria district mine inspector, second vice-president; Martin Bolt, secretary-treasurer, and J. A. Jeffries, St. Louis; L. E. Young, St. Louis; John Land, West Frankfort; George K. Larrimore, Springfield, and F. F. Tirre, St. Louis, members of the executive board.

### Priority Orders Upheld in Supreme Court Ruling

Congress has the constitutional right to authorize the issuance by the Interstate Commerce Commission of priority orders in the use of railroad cars in times of emergency, the Supreme Court held last week in an opinion delivered by Justice Holmes in a case brought by Edward P. Avent, Jr., of Michigan, from the federal District Court at Cincinnati, Ohio. That Congress has such power "no longer admits of dispute," the court declared.

Congress did not exceed its authority, the court declared, when in the Transportation Act of 1920 it authorized the commission, whenever it is of the opinion that shortage of equipment, congestion of traffic or other emergency exists in any section of the country, to suspend its rules as to car service and to make such reasonable rules with regard to it as in the commission's opin-

### Rate War Is Starting

Will the coal freight rate fabric of the Midwest and Northwest be completely upset and reconstructed again soon? This is a possibility in view of events of the week. The Interstate Commerce Commission has called to Washington for a Wednesday session representatives of many Midwestern lines as a result of the powerful protest the Illinois and Indiana coal producers have made against permitting the C. & O. and the N. & W. to make drastic reductions Dec. 5 on West Virginia and Kentucky coal going to Iowa and the Northwest. The L. & N. has announced a 15c. drop on coal to Minneapolis and St. Paul on Dec. 6 to meet the other two roads. These two cuts practically shut the Midwest mines out of a great market in which they have already suffered by the recent Lake Dock rate decision and there is much talk of a general reconstruction of rates. Meantime the Midwest hopes the commission will suspend the new low tariffs to the Northwest now dated Dec. 5 and Dec. 6.

ion will best promote the service in the public interest, and among other things to give direction for preference or priority in the transportation or movement of traffic.

In July, 1922, during the railroad shopmen's strike, the commission issued an emergency order regulating the use of coal cars at mines. It classified the different demands for coal and provided the order in which shipments could be made to meet them. In this order the making of gas fell into the second classification.

While the emergency order was in effect Avent ordered a shipment of coal from Kentucky to Union City, Mich., upon the representation that it was to be used by a gas company there. When the coal reached its destination it was diverted by Avent to a portland cement company, which was in the fifth classification. Avent was indicted for fraudulently inducing the railroads to ship the coal in violation of the commission's order. He pleaded guilty and was sentenced to a fine of \$2,000.

As the case presented other questions aside from the challenge of the constitutionality of the commission's preference order, it was sent to the Sixth Circuit Court of Appeals for such action as it might be necessary for that court to take in view of the decision rendered by the Supreme Court.

## Adopt Plan to Curb Waste of Timber And Encourage Reforestation

A broad program looking to drastic reduction in the waste of forest products and definite encouragement of reforestation was agreed upon at the National Conference on Utilization of Forest Products held in Washington, D. C., Nov. 19 and 20. Not only did the conference adopt the program but it provided a permanent organization to see that the program is carried out. This action is in contrast with many conferences where the enthusiasm is confined largely to the meeting itself and no provision for carrying on is made.

In providing the means for carrying out the resolutions of the conference a going organization was chosen. In view of the marked success which has followed the work of the Central Committee on Lumber Standards, of which John W. Blodgett, of Grand Rapids, is chairman, it was the sense of the conference that its scope should be enlarged so as to include in its objective the purposes of this conference, which are related to the work it has been doing.

The Central Committee on Lumber Standards was established two years ago at the suggestion of Herbert Hoover, Secretary of Commerce. Through it the industry has agreed upon a program of standardization and an elimination of excess variety which Secretary Hoover estimates will result in an annual saving of \$250,000,000. With the experience it has gained in this work and with the assistance of additional members with accurate knowledge of the two thousand uses to which forest products are put, another striking manifestation of beneficial co-operation among industries is predicted. The name of the committee is to become "Central Committee on Utilization of Forest Products."

### Eminent Committee Chosen

It is generally agreed that the successful outcome of the conference was due in no small measure to the committee on permanent organization and program, which was comprised as follows: A. C. Goodyear, president, Great Southern Lumber Co. (chairman); A. R. Joyce, Joyce-Watkins Co. (secretary); O. E. Bradfute, president, American Farm Bureau Federation; O. M. Butler, secretary, American Forestry Association; E. L. Carpenter, president, Shevlin-Carpenter-Clark Co.; Harry B. Curtin, president, National Hardwood Lumber Association; E. J. Curtis, vice-president, the Curtis Co.; W. Z. Georgia, president, National Wood Chemists Association; Elliott H. Goodwin, vice-president, U. S. Chamber of Commerce; Henry Graves, dean, Yale Forestry School; Charles A. Herty, president, Synthetic Organic Chemical Manufacturers' Association; Elmer C. Hole, managing editor, *American Lumberman*; John E. Lloyd, president William M. Lloyd Co.; B. S. Masters, National Association of Box Manufacturers; John C. Merriam, president, Carnegie Institution; J. Malcolm Muir, Associated Advertising Clubs of

the World; Warren R. Roberts, American Mining Congress; C. H. Sherrill, president, Sherrill Hardwood Lumber Co.; Henry W. Stokes, president, American Paper & Pulp Association; E. H. Stoner, president Western Pennsylvania Lumber Co.; R. Y. Stuart, commissioner of Forestry of Pennsylvania; W. B. Swift, International Harvester Co.; W. A. Thomas, president, Statesville (N. C.) Furniture Co.; Frank G. Wismer, president, National Lumber Manufacturers' Association.

It was this committee of men of large affairs who drew up the plan of campaign for the nationwide effort which is to be put forth. This is the way the committee states the problem:

"An adequate supply of timber is essential to the industrial development of the country and to the maintenance of present standards of living, as well as to the prosperity of the people and industries dependent on the forests.

"Regional timber shortages and consequent high cost already are making themselves felt to manufacturers and users alike and will become increasingly serious during the many years needed to get into effect an adequate program of timber growing.

"More careful utilization of forest products offers an immediate means of prolonging our supply of timber and should be recognized in the national program of forestry as of equal importance with timber growing and protection.

"Knowledge of better utilization has outstripped practice and should be applied wherever economically feasible as a necessary measure to reduce the drain on the forests.

"Through further research, understanding and co-operation it will be possible still further progressively to reduce the drain on the forests.

"Reducing needless drain will tend to lower the cost of raw material, will create additional sources of profit from material now wasted, and will lengthen the life of plant investments by prolonging the supply of raw material.

"The task of reducing these losses is a joint responsibility of the industrial, commercial, agricultural, governmental, educational and professional interests, and the general public."

### Western Kentucky Strike Is Slowly Breaking

It is reported from Central City, Ky., that the Gibraltar Coal Co. on Tuesday, Nov. 18, started cleaning up its mines three miles from Central City, and expected to start shipping this week. This is the second mine within five miles of the heart of the strike zone to start operations within a week, the Oakland Coal Mining Co. having started a few days ago. Miners are a little slow in reporting, but it is believed that crews will come in faster if there is no trouble.

## Complete Storage Report Of Engineers Now Ready; Consumer His Own Doctor

The report of the Coal Storage Committee of the American Engineering Council has been completed and will be issued to the public this week. James Hartness, former Governor of Vermont, president of the Council, says that the survey, called the biggest undertaking of its kind ever carried on in this field, shows that storage is the remedy for the nation's coal troubles and that the consumer should take the initiative in setting in motion the cycle necessary to provide at all times abundant fuel at less cost for industry and the home. Most of the recommendations of the committee have been published.

John Hays Hammond, who was chairman of the U. S. Coal Commission, appointed by President Harding, writes in the foreword to the report:

"This report on an engineering survey of the possibilities of improving the method of purchase, delivery and storage of coal should appeal to producers, carriers and consumers as the key to the solution of many of their troubles. The President's Coal Commission, learning of the purpose of the American Engineering Council to make such a study, assigned to it the task of conducting an extended engineering survey of the storage of coal.

"The commission and other government departments have collaborated with the American Engineering Council extensively, the survey has been conducted by over 400 engineers in leading industrial centers, and the report has been formulated by a committee of prominent engineers.

"The operation of the coal industry probably is beset with more difficulty than any other of the great American industries, due to prevailing intermittence of operation. If this evil could be removed it is plainly evident that a tremendous step would be taken in regularizing the coal industry and in helping other industries which are partly or wholly dependent on coal. The situation undoubtedly lies in greater storage.

"A reasonable accumulation in storage will permit of more even production throughout the year, deflation of the coal industry, continuous employment of labor, relief of congestion on railroads during their maximum demand season, removal of the coal 'feast or famine' conditions among consumers and many other allied troubles that are now felt as coal takes its course from mine to point of combustion. The fears of loss by the consumer have been studied by the committee and largely dispelled.

"In the past the operators have said that storage is the duty of the railroad whereas the carriers have contended that it is the duty of the consumer, and as a result storing has been neglected. This cycle must be broken, and a unified, economically sound practice established. The report wisely recommends and urges that the consumer, potentially the largest benefactor, should apply the needed balance wheel through himself initiating storage."

## Unions Threaten Boycott Against Stone Unless He Employs Union Miners

*Special to Coal Age*

El Paso, Texas, Nov. 24.—The United Mine Workers, failing to get the American Federation of Labor to condemn the Brotherhood of Locomotive Engineers for running the Coal River Collieries, in West Virginia, open shop, finally won a point Saturday in the Federation convention here. The convention unanimously passed a resolution empowering the executive council to exercise its good offices to adjust the dispute between the miners and engineers. If a settlement is impossible the council is to "advise the membership of all facts in the premises." This was a substitute for a resolution filed by William Turnblazer, a miner, at the beginning of the convention.

Advising the membership of "all facts in the premises" is a euphemism for a boycott. To warn the organized workers of the United States that Mr. Stone, head of a powerful labor union, is unfair to union labor in his capacity as director of the Coal River collieries would be followed by the withdrawal of trade unions from association in all capacities with the engineers' financial enterprises such as banks and mines, according to leaders of the Federation.

### "One More Chance" for Stone

The resolution, presented by the Committee on Boycotts, of which Frank Farrington, president of the Illinois miners' union, is chairman, was a substitute for two resolutions which asked the convention at this time to present all the facts in the case to the affiliated unions. Representatives of the railroad unions in the Federation appeared before the committee and pleaded for "one more chance" for Mr. Stone, whose union is not affiliated with the Federation. The committee complied with the request and in its substitute motion stated:

"Your committee finds that a strike has been in effect at four mines of the Coal River collieries in West Virginia since April 1 of this year, due to the failure of this company to renew its wage agreement with the United Mine Workers. We find further that the officers of the United Mine Workers have made repeated but fruitless efforts to reach a settlement with Warren S. Stone, chairman of the Board of Directors of this corporation, which assumes responsibility for its labor policy. We find also that this coal company has served eviction notices upon the union men who are on strike and has resorted to the employment of strikebreakers.

"In view of these facts and as a further constructive effort, your committee recommends the following:

"That the Executive Council of the American Federation of Labor be instructed to exercise its good offices to secure a settlement of this unfortunate controversy at the earliest possible date; that in the event of failure of such negotiations the Executive Council be instructed to advise the membership of the American Federation of Labor of all the facts in the premises."

**Holds One Job Ten Years**

Many producing companies are subject to much annoyance because of the rapid turnover in labor. Frank Furrence, pictured above, does not cause his employers much worry in that regard, however, as he has been with the same company for ten years. He has been a loader for the Island Creek Coal Co. at Monaville, W. Va., for the last nine years, working so steadily that his brass checks are so nearly worn out that he needs a new set.

John L. Lewis, president of the United Mine Workers, said that the officials of the miners' union were fully in agreement with those who offered the original resolutions and with the committee on boycotts.

He desired to spare the convention a long debate on the resolution, and spoke of having heard "mutterings in some quarters" of an intention to provoke a long debate. He warned those who had such an intention that the mine workers "can engage in a debate *ad infinitum*" if there were opposition to the committee's report. He would discuss the case in detail. Otherwise he would say nothing.

The motion was put. Discussion was called. There was no response and the resolution was adopted unanimously.

By his action Mr. Lewis disarmed his antagonists in advance and prevented a debate that would have lasted four or five hours and which would, undoubtedly, have been extremely acrimonious.

John L. Lewis, president of the miners, and Ellis Searles, miners' union publicity man, consider that the resolution strengthens the miners by enlisting the full influence of the Federation on their side. The resolutions committee proposed the substitute as more constructive than Turnblazer's report, which was altogether denunciatory. William R. Johnson, president International Machinists, previously opposed condemnation of Stone as unfortunate for the labor movement, but did not oppose substitute resolution.

The new situation gives the miners a chance to drag the whole case into the public eye again, which is all they hoped for.

## \$2,000,000 Electric Program Launched at Frick Plants

The H. C. Frick Coke Co. has awarded contracts for the complete electrification of five more plants and partial use of this power in two more in Fayette County, Pennsylvania. The work will commence at once and will require several months to complete. A total expenditure of \$2,000,000 is involved.

The five plants to be totally electrified are Leisenring No. 1, Lambert, Gates No. 1 and No. 2 and Ralph. At Leisenring No. 3 and Redstone electricity will be used for all work except hoisting coal. The maximum power demand for the seven mines will be 8,200 hp.

The company has been increasing operations during the past week. A total of 240 ovens was fired at York Run, Phillips, Continental No. 1 and Hecla plants. On Monday 175 ovens were added at Southwest and on Tuesday 200 were added at Lemont.

The plant of the Republic Iron & Steel Co. at Republic was reopened after being idle for a year.

At the Lynn plant of the Snowdon Coke Co. near Brownsville, 102 additional ovens were fired. There are now 270 ovens out of 300 in operation.

Effective immediately the Brier Hill and Nemacolin plants of the Buckeye Coal Co., a subsidiary of the Youngstown Sheet & Tube Co., will go on full time. These mines ship raw coal to Youngstown.

## Pittsburgh Mining Institute May Be Formed

Mine officials and those who aspire for this ranking in the Pittsburgh district are said to be discussing the formation of what may ultimately be termed the Pittsburgh Mining Institute. The purpose of the body, if it becomes a reality, will be to provide a clearing house for information on coal mining. It is proposed to meet two, three or four times a year for the discussion of practical problems.

At the tenth annual banquet held under the auspices of John I. Pratt, state inspector of the Seventeenth bituminous district of Pennsylvania, attended by mine workers, mine officials and affiliated interests, and held at Kaufmann's store, Pittsburgh, on the evening of Nov. 22, Bill McCoy proposed that such an institute be formed and John I. Pratt was requested to appoint a committee to consider the advisability of that step. About 1,100 persons were present, an attendance that is said to be a record for affairs of this kind.

The speakers of the evening were Capt. Edward Steidle, supervisor of the co-operative mining department, Carnegie Institute of Technology, who in a few words greeted those in attendance; A. R. Pollack, general manager of the Ford Collieries, who talked about the responsibility for safety in bituminous mines; Rush N. Hosler, general manager Pennsylvania rating compensation bureau, who interpreted accident and lost-time statistics in Pennsylvania mines, and William J. McCoy, who talked briefly on mining education.

## Union Drive in West Virginia Makes Scant Progress

The United Mine Workers has begun a drive to recover some of the ground lost in the southern West Virginia coal fields. A large force of organizers, at the instance of John L. Lewis, president of the union, have been holding meetings on Coal River and elsewhere in the Kanawha field in an effort to get the men back into the union and shut down the mines so as to bring about a recognition of the union. The effort has been attended by only partial success, for although some of the men who have been working non-union for the last two years have gone on strike, enough have remained at work to prevent serious interruption to operations.

Even two of the mines of the Coal River Collieries Co., owned by the Brotherhood of Locomotive Engineers, are operating. The third mine, it is understood, has been shut down. Other plants in the Boone County field have been shut down for a day or so but production has not been materially impaired. It is learned that where one or two companies have signed an agreement with the union operators are cutting expenses by not paying for certain kinds of work such as dead work.

So long as the market price of coal is low, some operators feel that the miners will work for the lower wage scale, but whenever the price of coal goes up, the miners will demand the higher scale and will rejoin the union unless they receive such increase.

## Slump in Coal Output Shown In Railway Report

There have been 6,916,658 tons less of bituminous coal dumped at Lake Erie ports during the present season up to Nov. 2 than were dumped during the same period of 1923, according to the report of the Car Service Division of the American Railway Association submitted to the Board of Directors at a meeting of that body held in New York on Nov. 18 and 19. During the period ending Oct. 1 bituminous coal on hand at the Head of the Lakes totaled 4,911,439 tons, a decrease of 181,462 tons when compared with the corresponding date of the previous year. The report says that during the season up to Nov. 2 there were dumped at Lake Erie ports 21,001,413 tons as compared with 27,918,071 tons during the corresponding period of 1923.

Dumpings last year were greatly in excess of any previous year, the report says, and resulted in heavy carryover of coal at the Head of the Lakes at the beginning of the 1924 season, which with the coal dumped to date at Lake Erie ports together with anticipated dumpings the balance of the season will provide an ample supply of coal at upper lake ports to meet all requirements.

Movement of coal to New England shows a marked decrease compared with last year. This failure to accumulate coal in that territory in greater volume during the season, the report declares, undoubtedly will mean a heavy movement during the winter and possibly under unfavorable weather condi-

Louis W. Huber

Recently appointed instructor in the department of metallurgical and mining engineering at Carnegie Institute of Technology, Pittsburgh, Pa. Mr. Huber was graduated in mining engineering from Illinois University in 1921. After obtaining his degree he went with the La Salle Carbon County Coal Co., Carbon County, Ill., and later was associated with the B. F. Sturtevant Co., of Chicago.

tions. Between Jan. 1 and Nov. 1 bituminous coal moved all rail to New England totaled 112,675 carloads as compared with 169,175 carloads during the corresponding period of 1923, a decrease of 56,500 carloads.

During the period Jan. 1 to Oct. 1 tidewater shipments of bituminous coal to New England were 7,255,591 gross tons, a decrease of 2,084,712 gross tons when compared with the corresponding period of last year. Shipments of anthracite to New England during the ten months of 1924 ended Nov. 1 were 245,831 cars, as compared with 319,057 cars in the corresponding period of 1923, a decrease of 73,226 cars.

The report shows that during the first 44 weeks of 1924 coal loading amounted to 7,092,598 cars and coke loading to 432,019 cars as compared with 8,158,120 cars and 628,083 cars respectively in 1923. Coal cars put in service during the first nine months of this year totaled 36,526, whereas during the twelve months of 1923 they amounted to 83,296 cars. Coal cars on order on Oct. 1, 1924, totaled 12,793, as compared with 26,541 on the corresponding date of 1923.

Coal production in British Columbia in September was 124,169 tons, which is 7,115 tons less than in August. The Canadian Collieries (D), Ltd., produced 37,013 tons during September, as against 41,708 tons in the preceding month. The Western Fuel Corporation of Canada, Ltd., had a September output of 35,206 tons, as compared with 41,413 in August. Slight increases were made by the Granby Consolidated M. S. & P. Co., Ltd., Cassidy; the East Wellington Coal Co., and King & Foster. The Nanoose Wellington Collieries produced in September 8,075 tons and in August, 8,122 tons. In the Nicola-Princeton district there has been some increase.

## \$30,000,000 Power Plant Planned on Lake Erie

A 400,000 hp. steam-electric generating station, to cost about \$30,000,000 and to serve as an important contribution to one of the Middle West's superpower systems, is to be constructed soon at Avon, Ohio, on Lake Erie, west of Cleveland, by the Cleveland Electric Illuminating Co., a subsidiary of the North American Co., F. L. Dame, president of the North American, announces.

"The new Avon station will tie in with the same company's Lake Shore station in Cleveland, which is the world's largest steam-electric plant under one roof," Mr. Dame said. "These two sister generating stations will, upon completion of the Avon project, have a combined power exceeding that now being taken from Niagara Falls."

This source of power is located at the northern end of superpower transmission lines running south to the Ohio River region, carrying energy into many iron and coal cities over the distribution systems of the Cleveland Electric Illuminating Co., the Northern Ohio Traction & Light Co., the Ohio Public Service Co. and the Ohio Power Co.

"In line with the practice of all the larger plants of the North American Co. subsidiaries," said Mr. Dame, "Avon station will be equipped to burn pulverized coal, an installation whereby fuel is ground into powder, mixed with warm air, and burned like gas at a temperature of 3,000 deg. By this method upward of 93 per cent of the heat energy in coal is being transformed into steam to turn the turbines as compared with 65 to 85 per cent in the old type crushed coal stokers."

## Coal Road to Extend Line

Extensive improvements are reported to be under way on the Wellsburg, Bethany & Washington Ry., which operates between Wellsburg, W. Va., and Bethany, Pa., preparatory to extending the line to Washington, Pa., from Bethany. The road was recently taken over by the Buffalo Valley Collieries Co.

Appropriations have been made by this company for the improvement of the roadbed of the electric railway system and additional appropriations are expected before the end of the year.

Two coal towns to house miners and workers are contemplated, one three miles north of Bethany, the other about three miles south of the village. The traction line divested of many of its tortuous curves, will be used to convey coal from the fields to Wellsburg. The problem of moving it to the railway, seven miles distant from Bethany, has been the main factor in delaying the work in the past.

Upon the completion of the improvements now in progress fifteen minute service will be offered between Wellsburg and Bethany with high speed cars. The remainder of the trip to Washington will require about an hour, upon the completion of that roadbed within the next two years.

# H. L. Doherty Urges Legislation to Curb Overproduction of Oil

Oil and Public Utility Operator Relies on State Action to Protect the Industry—Proposal Is Worthy of Study by Those Having Welfare of Coal at Heart

BY PAUL WOOTON  
Washington Correspondent of Coal Age

The news from Cleveland last week contained a valuable suggestion for the coal industry. Henry L. Doherty, an oil and public utility operator who long has been known as a champion of the public welfare regardless of the immediate effect upon his own business, came out flat-footedly, in an address before the National Petroleum Marketers' Association, for a program of legislation that would make it possible to end profligate output of petroleum.

In his paper Mr. Doherty goes into detail as to his proposals for legislation, but for the purposes of this article all that it is necessary to know is that he places chief reliance on state action. Apparently he looks to the federal government to lend its moral influence to the proposal. In fact, it is known that thought now is being given to calling a conference in Washington of petroleum producers to discuss ways and means of conserving our oil resources by checking the waste incident to overproduction.

Reference already has been made in this correspondence to the striking parallel between coal and oil in the matter of overproduction. It ravishes each industry and takes an enormous toll from the public and from posterity. In oil it has meant wanton waste of a diminishing resource. In coal it has meant the abandonment of hundreds of mines when only partly worked out. It has meant starvation wages when calculated on an annual basis. It has meant crushing losses to thousands of investors.

All of this has been clear to the coal industry itself, but that industry has not visualized so clearly how much its uncomfortable situation is due to overproduction in oil.

The total production of soft coal in the United States in 1923 was 560,000,000 tons. This looks sizable, but, as we now know, it includes a very large quantity put in storage which is being liquidated this year. The average production over the two-year period probably will be 510,000,000 tons. The average would have been much higher had there been nothing to interfere with the normal growth of new business. For a long period that normal growth was 17,000,000 tons annually. It has been five years since the war. Five times 17,000,000 tons is 85,000,000 tons. The country had reached a normal output of 520,000,000 tons in 1917.

The normal expectation of the coal industry, based on former experience, therefore, would be 520,000,000 tons plus 85,000,000, or 605,000,000 tons, which probably would have been the 1924 production had there not been a powerful competitor in the field. That business has gone to oil—partly to fuel oil, mostly to gasoline. That the big loss has been to petroleum is quite evident to anyone who will reduce the supplies of the several fuels to their heating value and compare the result. Here it is:

Per Cent of Total Heating Value in Coal and by Petroleum

Year	Anthracite	Bituminous	Total Coal	Oil and Gas (A)	Total Mineral Fuels
1923.....	14	73	87	13	100
1918.....	13	78	85	15	100
1924 (B)...	12	61	73	28	100

(A) Includes imports.  
(B) Based on preliminary estimates of production.

This shows where the coal market

has gone. Overproduction of oil has thrown on the fuel market ever increasing quantities of fuel oil and gasoline. It had to be sold at prices which would move each of them rapidly. Under present conditions there is no bottom to petroleum prices. Whatever may be said of the cost of production from pumping wells there is no bottom to cost of production from gushers. In 1923 California crude oil actually invaded Mexico. It went through the Panama Canal in great quantities for use on the Atlantic Coast, where it was sold under the noses of non-producers.

Mr. Doherty has raised a voice in the camp of the oil producers. The question now is, who will raise a voice among the coal producers?

Mr. Doherty's program for oil apparently is a good program for coal. None disputes that it is high time to limit the wasteful competition which sacrifices labor, standards of living and the coal resources at one and the same time. Mr. Doherty predicts that many oil operators will object to any such plan. It is certain also that many coal operators will object, but there is substantial opinion that it constitutes the chief prospect for their salvation. The oil industry is pleading for the right to prevent waste by co-operation. Its cause will be strengthened and success made more likely if the coal industry will join in the movement to procure the right to co-operate for the public good.

Northern Pacific Wants Coal

The Northern Pacific Ry. requests bids for its coal requirements from Dec. 1, 1924, to April 30, 1926, for the line extending from Jamestown, N. D., to Spokane, Wash. Not less than 500,000 nor more than 1,500,000 net tons will be required. The coal must be delivered f.o.b. cars on Northern Pacific Ry. tracks in as nearly equal monthly proportions as practicable in accordance with the company's requirements, commencing Dec. 1, 1924, and ending April 30, 1926.

Bids must be submitted to R. J. Elliott, purchasing agent, Railroad Building, 5th and Jackson Streets, St. Paul, Minn., by noon, Central Standard time, Dec. 1, 1924.

## Output and Value of Coal from Missouri Mines in 1923

(Compiled by U. S. Geological Survey)												
County	Loaded at mines for shipment (net tons)	Sold to local trade and used by employees (net tons)	Used at mines for steam and heat (net tons)	Made into coke at mines (net tons)	Total quantity (net tons)	Total value	Average value per ton	Number of employees				Average number of days worked

## Practical Pointers For Electrical And Mechanical Men

### Automatic Cager Speeds Loading and Unloading at Shaft Bottom

New Device Installed in Auxiliary Shaft of Illinois Mine—  
Hoisting Operation Made Continuous—No  
Limit to Number of Redumps

**O**LD tramming methods have long ago been abandoned in mines where high production records are made at low cost. Aside from the fact that automatic caging has resulted in savings and made possible large output the ease and safety with which the cars are placed on the cage are important factors.

Nearly every coal mine has some conditions about its caging problem which are different from others, but essentially the problem is one of accurately caging the car and getting the empty one off as quickly as possible. Many devices have been made to cage the cars but the best results are obtained only when the supply of loaded cars is co-ordinated with the system of placing them on the cage.

At the Donk Bros. Coal & Coke Co.'s Thermal mine No. 4 near Edwardsville, Ill., William Palecek, mine manager, and Fred Braske, mechanic, have developed a caging device which helps materially in speeding up the caging and hoisting of mine cars. Occasionally it is necessary to raise the mine cars to the surface through the auxiliary shaft and it was here that this device was installed, but usually the coal is hoisted in a skip in the main shaft.

#### NEARLY 100 PER CENT AUTOMATIC

The automatic caging equipment thus developed is interesting in that it is almost 100-per cent automatic, and as a result the hoisting operation is continuous. Two loaded tracks run direct to the shaft which is of the double-compartment type. Empty cars leave the cages on one side of the shaft and the loads enter on the other. All hoisting is done in balance, the cage at the foot being loaded while the one at the top is unloaded.

Between rails of the loaded tracks is placed a heavy steel shaft as shown in Fig. 1. On each shaft two car stops are arranged so that when one is in the up position the other is down. The purpose of these stops is to catch the axle of a car and hold it in place until released. The shafts are interlocked so that the rear car stop on one track is up when the rear stop on the other is down. Owing to the location and

position of the other two stops the same relation applies, namely when one is up, the other is down. If the rear stop on one track is up and ready to stop a car only the forward stop on the other track is in the engaging position.

#### HEAVY SPRINGS ABSORB SHOCK

The interlocking arm between the two tracks keeps the two bars so related to each other that when the rear stop on one track is holding a car the forward stop on the other track also holds a car. Heavy springs take the shock of a car when it bumps a stopping block and this has greatly reduced the repair and maintenance of the device and the cars.

On the end of each bar and extending into the sump is a heavily constructed crank or arm. The two cranks are so arranged and related to each other that as the cage descends to the landing a block on the cage turns the crank.

When the caging device is in service a car on one track is held against the forward stop while another car is held against the rear stop on the other track. When the cage descends, it strikes the operating arm on the first-mentioned track, and the car on the front stop passes onto the cage. This same operation releases the car held by the rear stop on the other track, and it proceeds to the forward stop on its track. At the same time the rear stop on the first track has raised and it holds the next approaching car. When the opposite cage descends it turns the bars of the caging device so that a car is loaded from the track leading to that side of the shaft and the other cars progress toward the cage as already described.

In this manner a car is caged from each track alternately. An added fea-

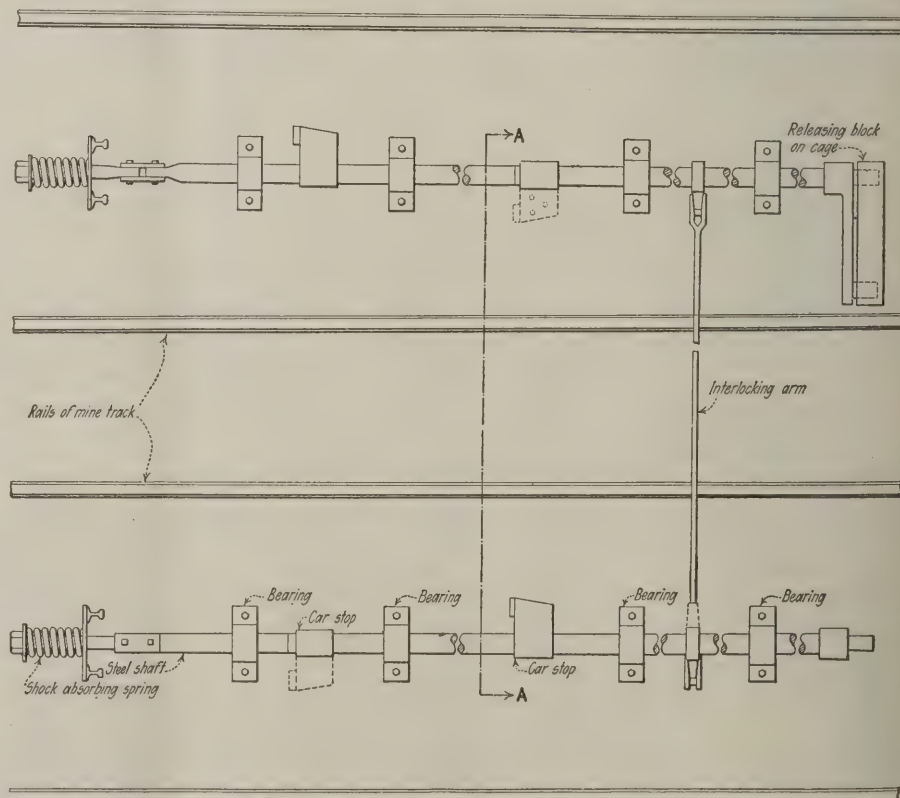

Fig. 1—Automatic Cager Permits Any Number of Redumps

The descending cage in one compartment releases a car which is caged immediately. At the same time a car on the opposite track is permitted to proceed toward the other compartment, but is held in position until the other cage comes down and releases it.

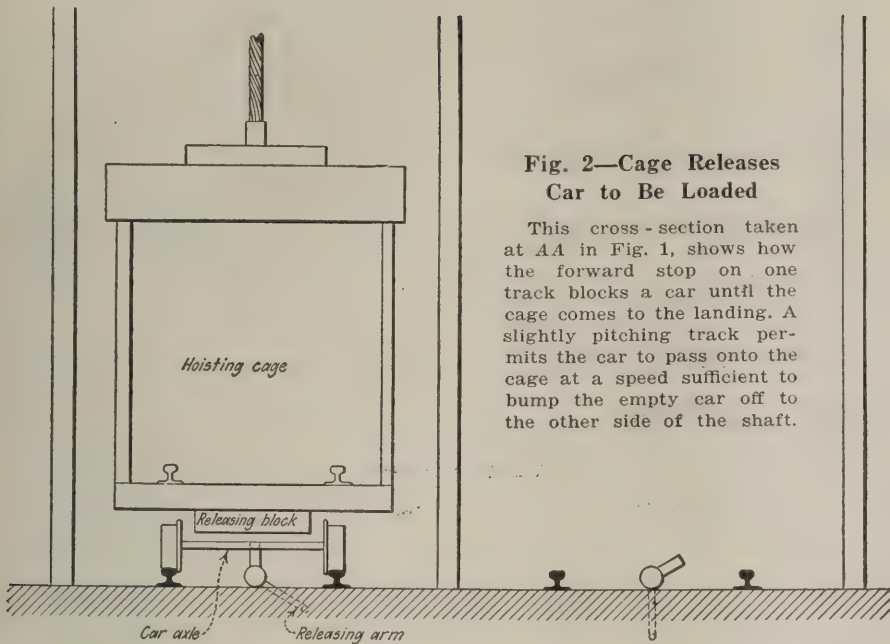

Fig. 2—Cage Releases Car to Be Loaded

This cross-section taken at AA in Fig. 1, shows how the forward stop on one track blocks a car until the cage comes to the landing. A slightly pitching track permits the car to pass onto the cage at a speed sufficient to bump the empty car off to the other side of the shaft.

ture of the device is that as many redumps as necessary may be made at any time without interfering with the sequence of operations of the caging device.

The designers have patented the mechanism and to date have been successful in supplying instructions and prints for its installation at other mines.

## Method of Equalizing Strain on Suspended Cables

With the use of alternating current for substations, hoists and pumps, within mines a suitable method for suspending three-conductor cables over bore-

### Strain Yoke Distributes Load

Each conductor must take its share of the load because of the equalizing effect of the strain yoke. Porcelain insulators prevent current leakages much better than wooden rolls, around which the cable is commonly wrapped in other types of bore-hole mountings.

holes has become necessary. The suspension should be arranged so that the strain cannot be concentrated on a single wire. Frequently due to the

arrangement of the supporting structure and the manner in which the cable is suspended, one conductor is compelled to carry the entire weight of the cable. This is not only overloads that wire but also causes accidents. When the wire breaks or slips the cable receives a sudden jerk and frequently the conductors snap and the cable falls, piling up at the foot of the borehole.

### PERFECT BALANCE OBTAINED

A novel method for equalizing the strains on the various conductors is shown in the illustration. The strain yoke is a heavy iron fitting built somewhat in the form of a tripod. An insulator is hung on each leg of the yoke, and each conductor is fastened to an insulator. The strain insulators prevent current leaks that otherwise would be caused by the insulation on the wire being broken where it is twisted and tied. A perfect balance between the three conductors is obtained because the strain yoke will tilt into a position so that each wire will carry its proportionate share of the load.

It will be noted that the borehole casing extends above the ground level. This is necessary to prevent water and especially snow from getting into the cable. It is always good practice to pour paraffin or wax on the outside of the cable, especially where the latter comes through the borehole casing. This seals the casing and conductor together so that moisture cannot work its way into the insulation.

The breaking of any one of the conductors is not merely objectionable because of the danger of a total failure of the line or because of the need of repair, but also because the breakage of the wire results in a phase failure which may ruin a motor.

## A Stunt Which Prevents Power Line Failures

Permanent line construction in these days necessitates the use of steel poles and crossarms. However, wood poles and wood crossarms are quite extensively used and thoroughly practicable. One of the greatest difficulties in the past has been due to the use of the same type and size insulators on steel crossarms and poles as were formerly used on wood poles and wood crossarms carrying the same voltage. It is quite obvious that short circuits and grounds are more likely to occur with steel poles which conduct electricity readily than with wooden ones which, when dry, do not.

### ONE BRACE PREVENTS LEAKS

A three-phase line on a wood pole is sometimes no better than the same line when mounted on steel members. The reason for this is that it is common practice to use iron braces on the crossarms and attach them close to the insulator pins. When this is done it is obvious that there is a metallic circuit almost directly from the insulator pin to the crossarm braces then to the other insulator pin on the same crossarm. To prevent such a circuit being formed it may be found advantageous

### Long Leakage Path Prevents Short Circuit

The left-hand crossarm brace on this pole was eliminated to prevent leakage of current from one of the top line wires to the crossarm braces and thence to the other top wire.

to use only one crossarm brace placing it on one side of the pole. This brace should be a heavy one. With this arrangement the current may leak along this crossarm brace to the pole but thereafter it would have to travel along a highly resistant path through the wood of the pole and the crossarm to reach either one of the other two line wires. By this method the liability to breakdowns on almost any wood-pole line can be greatly decreased at low cost. As the voltage on certain lines is raised to carry larger loads it is often inconvenient and expensive to change insulators. The plan suggested may obviate that necessity.

## Problems In Underground Management

### Explains Why Water of High Sulphur Content Causes Pump Failures

Coal-Mining Company's Experiments Indicate Six-Stage Pumps with Glycometal Impellers, Resist Acid—Centrifugal Action Separates Acid from Water

By J. S. O'FLAHERTY  
Chief Engineer, Central Coal & Coke Co.,  
Kansas City, Mo.

Some of the experiences of the company with which I am connected, in handling mine water heavily impregnated with sulphuric acid, may be of interest to other coal operators as well as to metal miners and pump manufacturers. In many operations the expense of handling sulphur water is one of the larger items entering into the cost of producing coal or other mineral.

In 1912 my company purchased two centrifugal pumps intended to perform certain specific work in a mine in Oklahoma. The water in this mine had a high sulphur content and the cost of pumping and of pump maintenance was excessive. One of these pumps was a three-stage machine while the other had four-stages. In both pumps the impellers were of bronze, and the casings were made of acid-resisting metal selected from samples submitted for test by some of the largest and most reliable pump builders in the country.

All tests of this metal were conducted in both standing and running water in the mine in which the pumps were to operate. When these machines were purchased it was the intention to operate them under different heads in different locations in the mine. Through a change in plan, however, they were installed side by side, pumping out of one drill hole, each pump working a 12-hr. shift. In the course of time the shell of the three-stage pump was destroyed by the action of the acid water. Having portions of the pump still in good order yet on hand, sufficient repairs were ordered to again put the machine in good condition. The shell of the four-stage pump was still in good shape when the second casing of the three-stage pump was practically gone.

For a while I was of the opinion that a better grade of acid-resisting metal had been used in the four-stage pump. The two machines, however, were operating at the point for which the three-stage unit had been specifically designed. In time it occurred to us that the number of stages in the pump might have something to do with its life. Further experimentation proved this to be the case.

We now use a six-stage pump under

the conditions where formerly we would have used a three-stage machine. Furthermore, by using impellers made of glyco metal we have imparted indefinite life to our pumps when handling the same water that formerly caused no end of trouble.

My explanation of this is as follows: Sulphuric acid is comparatively heavy, having a specific gravity of 1.849; consequently the impellers act as separators, concentrating the sulphuric acid against the shell or casing. As a result the slower the rotational speed the less the separation of water from the acid, and the greater the number of stages the less the velocity of the water.

Chemists to whom the above was shown state that the affinity between sulphuric acid and water is so strong that the two liquids cannot be separated or the acid content appreciably concentrated by centrifugal action.

Perhaps some *Coal Age* reader has had experience similar to that above related and can explain this phenomenon.—  
EDITOR.

### At Crossover Double Rail Lifts False Flange Above Track Rail Being Crossed

Where the Fourth East entry crosses the Second Main South haulageway in the Springdale mine of the Allegheny Pittsburgh Coal Co., Logans Ferry, Pa., a substantial crossover has been laid which possesses at least one feature worthy of note. Beside the usual crossover rails, on which the wheels of rolling stock run, and guard rails to insure safety to a trip in passing the junction, an outer rail is matched with each of the track rails in the crossover as shown in the accompanying illustration. These outer rails are placed close to the track rails. The balls of both rails touch each other and lie in the same plane.

Each end of the outer rails is tapered in the vertical plane to form a slight incline which gently lifts false-flanged wheels of rolling stock up and over the track rails being crossed, thus eliminating violent impacts between the false flanges of the wheels and the rails being crossed. The outer rails form a track in the crossover on which the unworn parts of wheels run,

#### Stilling the Cry, "They're Off at the Crossover Again"

Wheel treads are made wide for safety. If they weren't wide cars would leave the track at any point where the distance between the rails greatly exceeded the gage. But that widening of the tread unfortunately gives it an unworn exterior area, and at this crossover an extra rail is placed so that this unworn area supports the wheel, lifting the worn area clear of the rails being crossed.

# Production And the Market

## Coal Business Has Fleeting Revival of Interest With Fall in Temperature

A partial sop to the justly disgruntled coal trade came along last week in the guise of a blast of rough weather, but—the usual insect in the salve—while it was unusually severe it didn't last long enough. Therefore, although there was a sudden revival of interest in coal it subsided almost as quickly as it appeared and conditions resumed the listless aspect that had been in evidence for several weeks. The paradoxical wish of the coal industry still is for more weather—the worse the better. And unless a stretch of seasonable temperature puts in an appearance soon the producer will be up against it harder than ever with the end of the lake season close at hand and heavy tonnage to be deflected into other channels.

### Industrial Improvement Is Spotty

The era of prosperity expected to follow on the heels of the election has thus far fallen far short of prognostications. Though surveys of industrial conditions indicate an improvement, the pickup has not been sufficiently general—being quite spotty in fact—to give the impetus to business expansion that would pull the coal trade out of the rut. As New England industries have been conspicuously sluggish for some months more than ordinary interest attaches to the resumption of operations this week on full time by one of the large Fall River textile plants.

The anthracite trade felt the stimulus of more seasonable weather, especially the retail end—the producers scarcely needed it, as they have not entirely caught up on October orders. Stove is in greatest demand, except in Philadelphia, where chestnut has forged to the front. Egg and pea are listless and there is perhaps a slight improvement in the steam sizes. Independent prices show a firmer tendency with little material change in the range of quotations.

Coal Age Index of spot prices of bituminous coal at least is holding its own, standing on Nov. 24 at 170,

the corresponding price for which is \$2.06, the same as for the preceding two weeks.

A further gain in activity was made at Hampton Roads last week, dumpings of coal for all accounts during the seven-day period ended Nov. 20 totaling 369,793 net tons, compared with 356,603 tons handled during the previous week.

Movement of coal across the lakes is unmistakably on the wane, dumpings at Lake Erie ports during the week ended Nov. 23, according to the Ore & Coal

Exchange, being as follows: For cargo, 704,930 net tons; for fuel, 28,698 tons, compared with 753,405 and 30,875 tons respectively during the preceding week.

Despite the celebration of Armistice Day, which cut operation about 40 per cent, the output of bituminous coal improved perceptibly in the second week of November, when, according to the Geological Survey, 10,122,000 net tons was produced. This was an increase of 791,000 tons over the preceding week, according to revised figures. Incidentally this is the first time since February that production has exceeded a corresponding week of 1923. Election Day tended to limit output of anthracite, but nevertheless 1,674,000 net tons was produced during the week ended Nov. 15, compared with 1,592,000 tons in the previous week and 1,669,000 tons in the corresponding week of 1923.

### Estimates of Production

(Net Tons)

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Feels Slight Pick-up

A little more business was available all along the line in Midwest markets during the week, though domestic coals have not started any climb worthy of cheers. Most producers are wary of overproduction and therefore the markets have not been flooded with anything. This firms up most coals. Steam sizes have stiffened a shade in and around Chicago and a further improvement is expected unless a cold snap of real iciness should induce a sudden heavy production of lump and egg. Smokeless domestics could not maintain their top of \$4.25 and sank to \$4, but there has been a steady mine-run trade even though the price never passes \$2. Anthracite is reasonably active throughout this territory despite keen oil competition.

Cool weather came along just in time to save the domestic prices in the southern Illinois field. All domestic sizes, with the exception of lump, were beginning to pile up and lump was slow at several mines, with the result that in one or two places lump prices were good but egg suffered and nut was a drag on the market. Railroad tonnage is light, cars are plentiful and the movement is good. Mines are getting from two to four days a week and all coal has been moving under pressure.

In the Duquoin field conditions are similar to the above except that prices are weaker. Weather has been favorable and prices are such that Duquoin coal will move. In the

Mt. Olive field conditions have been unusually bad but cold weather has put a little life into that region's domestic trade. There is some domestic coal moving northwest and steam is pretty well taken up on contract with no change in prices. In the Standard field up to the present there has been no movement and conditions have been unusually bad, most coal being sold at below cost.

A little cold weather has spurred the St. Louis market just a trifle on cheap grades. There is nothing doing in anthracite, smokeless and coke. Carterville is moving rather freely but the small orders which are most numerous are for the cheaper grades. Country domestic demand for Mt. Olive or better grades is fairly active. Local wagon-load steam is very good, while carload steam is soft and with little demand. Country steam is rather hard to find, with nothing moving out of the Chicago market.

### Better Omens in Kentucky

Demand for Kentucky coal over the week has been fair, but offerings at Louisville have been heavier due to larger tonnage production in western Kentucky and slumping off of Lake movement from West Virginia and eastern Kentucky. Retailers haven't been moving much yard stock because of mild weather and are refusing to buy. The result has been that there is a good deal of prepared coal on track in western Kentucky awaiting billing. Eastern Ken-

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924		1923	
	Nov. 24	Nov. 17	Nov. 10	Nov. 26
Index .....	170	170	170	186
Weighted average price .....	\$2.06	\$2.06	\$2.06	\$2.25

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

tucky also has unsold coal on track and has been active in an effort to move egg and 2-in. lump sizes.

Steam demand has been fair for screenings, but not much mine run is being taken, although total industrial movement has been good since election.

Of course there is a fair movement to retailers in the North, who are getting more cold weather. However, prices are a shade weaker on prepared. There is very little eastern Kentucky block quoted at over \$3.25, and not much sold at over \$3, while some good coal has been offered at \$2.75. Western Kentucky is still asking \$3 for block, but the price is being shaded.

Screenings are firmer as a result of lighter production of prepared. The western Kentucky field has advanced to 85c.@\$1 a ton quoted, and supplies are said to be scarce at these prices. Some screenings in eastern Kentucky are quoted at 85c. but most houses are asking 95c.@\$1.10.

### Northwest Is Busy

Stocks of coal on docks at Nov. 1, according to figures just released, give an accurate picture of the condition at Head of the Lakes. This year the docks hold 4,751,352 tons of bituminous as against 5,369,529 last year at the same time, and 543,340 tons of anthracite as against 138,982 last year. Obviously the bituminous market will not be glutted this year and the anthracite now on hand will assure the Northwest that there will be no shortage.

Only one cargo of anthracite was received last week and at the same time 36 cargoes of bituminous came in. Twenty-three cargoes are reported en route and one of these is anthracite.

The feature of the Head-of-the-Lakes market still is Pocahontas. The demand is insistent and several docks have received additional cargoes to help out. The price took another jump in lump this week and now stands at \$9. With the jump, however, mine run remains at \$5.50 and screenings at \$4.50. Pocahontas lump was \$7 for October. Other prices, both in hard and soft coal, remain the same.

Docks are on the jump and are working overtime to get shipments out. Last month, it will be remembered, was the biggest so far this year, and this month bids fair to pass it. One dock is two weeks behind in its orders.

At Milwaukee a drop in temperature during the week, with snow as a reminder of conditions soon to be expected as a matter of course, caused a betterment in the inflow of orders for fuel for a day or two, but things snapped back with a rise of the mercury, and dealers report a quiet market. There has been some improvement in getting stock from the mines, which have been catching up because of slower demand. Pocahontas has been advanced in price 25c. to 50c. a ton, the latter advance on the nut size. The Milwaukee retail price is now \$11.25@ \$11.50.

Milwaukee receipts during November, including the 19th, were 23,500 tons of anthracite and 283,235 tons of bituminous coal, making the season's totals thus far 716,794 tons of anthracite and 2,346,609 tons of bituminous coal, or 3,063,403 tons in all. Receipts for the same period of 1923 were 862,324 tons of anthracite and 3,000,162 tons of bituminous coal—3,862,486 tons in all.

### Western Domestic Is Slow

Kansas screenings, which have been selling several weeks at \$2, are quoted at \$2.25@ \$2.35 now. The surplus of this grade which accumulated during the early season period of heavy domestic demand has been moved and it is now the domestic sizes that are dragging, with mines working only about half time. Production in Arkansas and Oklahoma also is very light, the result of warm weather.

A slight stimulation in the production of domestic coals was noted in the Colorado market during last week, but not to such an extent as one familiar with previous seasons would expect for this time of the year. The remarkably warm weather prevailing throughout Colorado and the regions where Colorado coal is marketed is puzzling others than the weather man. However, Colorado mines worked on an average of 31 hours last week with only 18 per cent of the total working time lost on account of "no market." Prices are firm.

In Utah production is increasing as a result of colder weather. The best industrial customer is the metal mining industry. The sugar making campaign fell nearly 40 per cent short of normal and there may be some surplus coal left in sugar factory yards. Northwestern business is improving and the California trade is holding up well. Dealers, who have already moved a good deal of coal to householders' cellars, are not buying heavily at the moment.

### Ohio Markets Lack Vim

Sales of coal in the Cincinnati market have fallen off materially during the last week, in spite of the active movement of lake coal in winding up the season. There has been a slight increase of steam and byproduct orders, but a large falling off of domestic orders. Most retail yards are full, but the colder weather of the last week served to relieve them a good deal. The off situation has been marked by the reappearance of distress coal, though not to an amount to prove demoralizing. Many mines have had to shorten production and available mine tracks are full of loaded cars. Mine-run both in low and high volatile continues to drag in the West, which is customarily its best market, but this condition, due to earlier overshipment, is only temporary. The tidewater demand for smokeless mine-run continues off and the price is below the profit-making point. West Virginia and Kentucky operators have had notice that final shipments on outstanding orders for lake coal must be made on or before Nov. 26.

While colder weather has stimulated retail trade at Columbus, no effect is noticed in production and distribution. Smokeless and splints are rather strong at former levels, but Hocking, Cambridge and Pomeroy coals are weak and featureless. Prices have not moved to any extent. Steam business is rather dull, reserves are fairly good and buying is mostly from the open market, as demurrage coal is still rather plentiful. General manufacturing has not increased to any extent. Screenings are slightly stronger as a result

of reduced output of prepared sizes. Production is not large in any section of the southern Ohio field.

At Cleveland there has been a marked stiffening in spot prices on slack and nut and slack of 10c.@15c. per ton, the result of diminishing supply of these grades due to the cessation of production for shipment in the Lake trade and the further fact that steam users did little stocking when slack was plentiful.

### Demand Slightly Better at Pittsburgh

Demand has been improving slowly at Pittsburgh since the election, but not enough to make up for the previous lull without a corresponding decrease in production. Railroad consumption is good, but stocking is below normal. The steel mills are now running a trifle above their average in the past six years. Domestic coal demand has been poor for this time of year, due to mild weather, and prices have failed to stiffen. Nut is particularly hard to dispose of and slack is in unsatisfactory demand, but steam slack has avoided falling below \$1.

A slightly better tone pervades the central Pennsylvania coal market since the election. Orders are increasing slightly and although production has been slightly lower this is accounted for by four holidays during the month, when many miners were off duty. Output for the week ending Nov. 15 was 14,243 carloads, compared with 14,436 carloads the previous week.

Trade at Buffalo continues quiet with prices no higher. The steel trade has improved a little and business is in a healthy condition. The movement of coal is very free. Cars are not at all hard to get and they arrive at destination promptly. A sudden cold snap improved buying a little, but it lasted only two or three days. Quotations are as before, with a slight stiffening in slack.

### New England Markets Listless

In New England buyers seem almost wholly without interest in the current market and prices are again somewhat depressed in consequence.

The Hampton Roads situation seems to have entirely lost the favorable tone that was noticed a few weeks ago. Prices f.o.b. vessel have again slipped to lower averages, \$4.20 having been mentioned in the past week for navy acceptable grades f.o.b. vessel. The recent sale of locomotive supply coal by the Island Creek interests to New England railroads in considerable volume, displaying a large tonnage of high volatile from other districts in West Virginia, and has occasioned much comment.

For inland delivery high grade Pocahontas and New River are an easy purchase at \$5.35@\$5.40 per gross ton on cars Boston, with Providence and Portland prices 15c.@35c. higher, depending upon the urgency of sale. This situation continues to exclude even the highest grades all-rail from central Pennsylvania.

Dumpings via the New York and Philadelphia piers are at a minimum. The tonnage is not only relatively small but is confined almost exclusively to gas-producing coals and other specialties that in the main are unaffected by competition of the smokeless coals from Southern ports.

### Signs of Life Appear in Atlantic Markets

A little more activity has appeared in the New York market. Buyers are inclined to display a little more interest and coal movement is somewhat better than last week. Contract holders are more anxious about their full quota and there is not so much free coal available as a result. Not

much improvement is looked for, however, until after Jan. 1. Arrivals at tidewater continue to increase but shippers appear to be able to dispose of the surplus without much trouble. Quotations continue on last week's basis.

Colder weather has stirred up interest in the Philadelphia market, though buying has not increased much. Ordering on contracts is heavier and there is some storing for winter. Offering of slack has fallen off slightly but demand from retailers has increased. There is not much life at tide.

At Baltimore there has been no response by coal buyers thus far to the prosperity talk. Prices remain at points that bring little, if any, profit to producers, and offer little incentive for sales work by jobbers. On several days of the past week there was not more than one vessel at any time at the piers taking export coal.

Birmingham trade is devoid of much activity. Such seasonal industries as oil mills and steam electric plants are the principal buyers in the spot market, there being little increase in the tonnage taken by year-round industries as compared with recent weeks. Railroads are taking minimum deliveries on contracts and apparently no buyers on contract are increasing reserves. Domestic sales are confined to orders for a few cars for shipment here and there over the territory. Quotations are fairly steady and but little domestic or steam is produced in advance of disposition.

### Spurt in Anthracite Market Short-Lived

There was a slight revival in the anthracite market at New York early in the week, but it did not last long. Lower temperatures caused a sudden spurt in demand on the retailers, which was reflected in the wholesale trade, but bins were soon refilled. Independent prices steadied with the increased demand, but the range doesn't show any material change. Stove leads in demand, but egg and pea move slowly. The situation of the steam sizes has not changed. Early in the week some shippers offered egg coal at tidewater on a basis of \$8.25 per ton at the mines, but this was soon cleaned up.

Unusually cold weather at Philadelphia has caused a strong retail demand, but producers hardly needed a stimulant of this kind, as they have not altogether caught up with orders. Stove and nut are most in demand, with the latter now in the ascendant. Egg is giving more trouble than pea. Retail prices have strengthened. Steam sizes are in much better demand.

Demand is only moderate at Baltimore although spurred into some action by a cold snap during the week. Much is hoped for as a result of the drive about to be started to educate the people to burn buckwheat coal. Yards are fairly well stocked to meet all demands.

At Buffalo the demand for anthracite has been helped materially by colder weather and retailers are really busy for the first time since last winter. Consumers are still seeking substitute fuel, however. The latest is a shipment of blue star semi-anthracite from southern West Virginia. The price is \$4 to \$5 below anthracite, but the coal carries considerable volatile, though it is claimed that it is much above regular anthracite in heat units and lower in sulphur and ash.

## Foreign Market And Export News

### Business in British Market Improving But Still Below Normal

The improving tendency in the South Wales market is patchy, and the recent heavy gales have disorganized shipping, holding up consignments and causing more stoppages at the pits. The sale of 300,000 tons of best admiralty coal to prominent Italian exporters for 1925 delivery at 26s. f.o.b. is reported from Cardiff. On the whole, however, foreign demand is disappointing. Complaints of German competition are unabated, and it is reported that Germans are giving three to six months credit against the thirty days offered in the South Wales market. Several other collieries are reported on the verge of stopping.

Several contracts have been renewed, among them that with the Somerset and Dorset Joint Railway for 1,000 tons of coal per week for the next year. Several other smaller contracts have

been placed and others renewed, but in no case is the price revealed, which leads to the impression that prices now are below those of expiring contracts.

The Newcastle market has improved very slightly, though operators are finding difficulty in meeting German competition; British prices, though at their very lowest, are still about one dollar per ton above the German figures. None of the pits has reopened, and, according to the principal of one large group in north England, there is every prospect of further stoppages unless business improves.

A cable to *Coal Age* states that production at the British collieries increased in the week ended Nov. 8, when the output was 5,137,000 tons, according to the official reports. This compares with 5,043,000 tons in the week ended Nov. 1.

### French Markets at Standstill; Stocks Unimportant

The French coal market remains in a sort of privileged position in that while Belgian supplies of industrial coal are excessive, French stocks of corresponding grades are just normal and those of house fuels practically nil. Demand for industrial coal is limited and that for house fuel, active at the end of October, is at a momentary lull due to unusually mild weather.

Imports of Cardiff-Swansea and Newport coals fell away in October to 667,000 tons, compared with 1,008,000 tons in the corresponding month of 1923. This was due partly to the further appreciation of sterling, firmness of prices at the shipping docks and receipts of fuels from Germany.

German reparation deliveries having virtually stopped since Oct. 28, when the M.I.C.U.M. retired from office, a meeting of French, Belgian and Italian representatives with delegates of the German mines and cokeries was held in Paris under the auspices of the Reparation Commission and an agreement was

quickly arrived at. The apportionment of reparation fuels to the Allies will be fixed by the Reparation Commission, France's share to be about 600,000-650,000 tons per month dating from November.

The supply of coke to the O.R.C.A. in October was 269,805 tons, of which 11,555 tons was received during the last two days of the month. From Nov. 1 to 12, 6,746 tons was received.

### Trade Slow at Hampton Roads; Price Tendency Firmer

Business at Hampton Roads is slow, although prices show a tendency to stiffen, due to the advent of winter weather. Inquiries have increased somewhat and prospects are brighter.

Coastwise business has improved and bunker movement is good, but practically no foreign business is being booked. Little prospect for increase in the latter trade is seen. Coastwise movement is expected to increase rapidly and the bunker trade has every indication of continuing upward.

The tone of the market is firm. Though few contracts are in the market, domestic business was improved on substantial lines. Supplies at tidewater have improved somewhat.

## News Items From Field and Trade

### ALABAMA

New coal washeries of medium capacity will be constructed by the Pratt Fuel Corporation at its drift mines at Dora and at its Jagger operation. The plants will cost about \$60,000 and \$20,000 respectively, according to announcement.

Frank Nelson, Jr., formerly president and principal owner of the Nelson Coal Corporation, and S. L. Yerkes, of the Grider Coal Sales Agency, who formerly operated the Burnwell Coal Mining Co., have been elected directors of the Pratt Fuel Corporation. The properties of the former two companies were absorbed by the latter a short while ago.

Walker County celebrated its 100th anniversary as a sub-division of the state recently at Jasper, Ala. A contest was held to determine what factor had contributed the most to the up-building and development of the county to its present position of wealth and influence and "Coal" was voted this distinction by the crowning of L. B. Musgrove, a pioneer developer in the Walker County field as "King."

The School of Mines at the State University, University, Ala., operated under the direction of the U. S. Bureau of Mines, is making an addition to its laboratory to accommodate new equipment recently acquired. A small coal washery has been donated to the school by the Montgomery Coal Washer & Mfg. Co., of Birmingham, and concentration tables and other equipment have been added to aid in the treatment and determination of coal samples.

The Joseph A. Holmes Safety Association, which has organized chapters throughout the Alabama coal fields, is conducting a campaign for the prevention of haulage accidents in the mines, it being stated that this class of accidents is responsible for about 16 per cent of the fatalities in the industry. Meetings are being held throughout the district, each being addressed on this subject by an official of the association or some representative of the Alabama mine inspection department or U. S. Bureau of Mines, which latter agencies are co-operating in all efforts being put forward for the prevention of accidents in mining operations.

### COLORADO

The State of Colorado produced 123,892 tons less coal during the first nine months of the year than it did in the same period of 1923.

The Chandler mine of the Victor-American Fuel Co. broke all its previous

monthly production records when it averaged nearly its maximum of 850 tons a day during October. This mine is in the Canon City field.

D. E. Davis, superintendent at Oak Creek for the Victor-American Fuel Co. in Routt County, is in California for a long vacation.

Colorado was not the most dangerous coal mining state in the Union during September. National statistics on coal-mine accidents for the month show 186 deaths for 48,624,000 tons produced, or a national fatality rate of 3.83 deaths per million tons of coal. Colorado's rate was but 3.20 for the month.

F. O. Sandstrom, secretary and traffic manager of the Colorado & New Mexico Coal Operators Association, and Harry F. Nash, vice-president of the Oakdale Coal Co., were in Washington, D. C., during the week of Nov. 17, representing the Colorado operators in the Missouri River rate case, which is at present before the Interstate Commerce Commission for final hearing. This case was filed by the Colorado operators in September, 1923, in order that the commission might eliminate the discrimination in the rates between Colorado fields and other producing districts to the Missouri River.

### ILLINOIS

The Peabody Coal Co. has reopened its mine No. 9, at Langley, which had been closed several months. It is expected that 500 men will be employed all winter.

Eighty men are on the payroll of the Rutland Coal mine, at Rutland, which was recently opened by Ottawa men. Rutland is now producing third vein coal.

The United Electric Mine Co., Danville, is negotiating for a large acreage north of Rushville, with a view to opening a big strip mine. Several options have been closed upon land and more are pending. The company is, now operating a mine between Cuba and Lewistown on the Galesburg-Havana branch of the Burlington, where it began taking out coal last February. The output of that mine is now thirty cars per day. The coal on the farms near Rushville, which are now under lease, is under from 30 to 40 ft. of cover. It averages 5 ft. in thickness.

Crescent Mine No. 1, in Marsh Creek Hollow, near Peoria, has begun operation on a half capacity basis after having been idle since March 29. This operation will give employment to 250

men. With the opening of this mine about 40 per cent of the miners in the Peoria territory are now employed. This is an increase of 30 per cent over the total employed sixty days ago.

The Tiger mine at Cuba, has resumed work after having been closed down for the last four months.

### INDIANA

Reports that the Vandalia Coal Co., operating some of the largest mines in Indiana, is experimenting with a "new process of mining," to which miners are taking exception, have been refuted by officials of District No. 11, United Mine Workers. "It is true the Vandalia Coal Co. is experimenting with the Joy loading machines, but the miners are not objecting to this," John Hessler, president of the miners, said.

### MISSOURI

A. Burt Champion, former vice-president of the Matthew Addy Co., has opened an office in St. Louis, where he will sell pig iron, coal, coke, charcoal, fluorspar and alloys.

### PENNSYLVANIA

The Shamokin Collieries Co., which is headed by Boyd C. Osler, formerly of Hazleton, is following the lines suggested by A. J. Jessup, general manager of the Jeddo-Highland Coal Co., and is going after the small sized coal trade.

To protect the new Fort Jenkins bridge at Pittston from damage by mine caves and settlement of the surface, the county commissioners have entered into an agreement with officials of the Pennsylvania Coal Co. for the purchase of the coal under the piers and abutments and for a certain radius beyond.

Consolidated Coal & Coke Co., of Butler, resumed operations Nov. 17 at its mines at Nicola, Armstrong County, after a shutdown since last April. Fifty men are employed. The company resumed operations at its Fennelton mines in Butler County three weeks ago.

Activity is increasing in the Connelville coke region. The Republic Iron & Steel Co. resumed operations last week at the Republic mine, which had been idle more than a year. No ovens are being fired but the mine will operate 100 per cent. The H. C. Frick Coke Co., however, fired 200 additional ovens at its Lamont plant. The Fayette Coal & Coke Co. has resumed

work at the Shamrock operation. The Linn plant of the American Coke Corporation, which was taken over at receivers' sale about a year ago by the Union Trust Co., resumed mining last week under the name of the American Coke & Fuel Co., of which George Batton, of Pittsburgh, is the head. The Snowdon Coke Co. has fired 100 more ovens.

The Cosgrove-Meehan Coal Corporation, of Johnstown, has contracted with the Roberts & Schaefer Co. for the installation of a Marcus screen and R. & S. loading booms at its new tippel at Foustwell.

Announcement has been made that Concrete City, the model settlement of the Glen Alden Coal Co. in the lower end of Hanover Township, is to be razed soon after Jan. 1. The tenants of the houses, who work at the various collieries of the company in the section, have been notified to vacate the premises not later than Dec. 1. Company officials say that the settlement is to be abandoned due to the action of the State Health Department in demanding that sewers be installed in the section, which would entail an expense of \$200,000.

Mine inspectors of the state are not employees within the meaning of the state administrative code, according to a decision rendered by William A. Schnader, special Deputy Attorney General. The ruling has just been given to P. S. Stahlnecker, secretary to Governor Pinchot and secretary of the state executive board. They are departmental administrative officers of the state, it is held.

An unusual set of lessons for use by Pennsylvania coal miners attending evening classes has just been completed at Pennsylvania State College, under the direction of N. E. Hubbel, associate professor of industrial education. The aim of the lessons is to prepare ordinary miners to take state examinations for official positions in mine work. Separate sets are to be used in the bituminous and the anthracite districts. The course requires two years of weekly class attendance during the winter

months. The lessons have been approved by the State Department of Mines and the State Department of Public Instruction. One thousand six hundred miners were enrolled last year and this year the number will exceed 2,000. The lessons have been made available at cost to those who cannot attend school.

To accommodate the large volume of coal which is hoisted daily at No. 4 slope, Alaska colliery of the Philadelphia & Reading Coal & Iron Corporation at Mount Carmel, a new high-powered electric engine is being installed at the head of the incline. A concrete engine house has already been built. On account of the immense size of the new engine a floor several feet deep has been placed. Hitherto three cars a trip were drawn to the top of the incline in ten minutes. With the high-powered engine it is expected that at least four cars will be drawn on each trip and it will take only two minutes.

The board of directors of the McKeesport Coal & Coke Co. has called a special meeting of its stockholders, to be held at its office, 1406 First National Bank Building, Pittsburgh, Dec. 2, at 2 p.m., for the purpose of (1) voting for or against an increase of the capital stock from \$1,200,000, to \$1,600,000, and (2) approving or disapproving of the creation, out of such increase of capital stock, of 2,000 shares of preferred stock of the par value of \$100 per share, entitled to receive a fixed yearly cumulative dividend of 7 per cent but no more, before any dividends be paid on the common stock.

By a decision of the State Supreme Court, it is ruled that mine owners "have no right of any kind to drain their mine waters into streams, considering the public use made of their waters, and that their so doing constitutes a nuisance which must be restrained." In the anthracite region the outlet for mine water has always been the creeks and rivers which flow through the sections where mining operations are conducted. The opinion was handed down in the case of the Pennsylvania R.R., the Mountain View Water Co. and other water companies

against a group of Fayette mine owners. Justice William I. Schaffer wrote the opinion. It provides that a pure water supply is a public necessity paramount to any other consideration.

Thomas J. Kennedy, president of district No. 7, declared that the most important subject in connection with coal mining to be considered by the next legislature is the electrical hazard. Other union officials condemn the use of electricity in the mines as "needless and dangerous." A new law should be drafted to make impossible the danger from the general use of electricity, some of the miners urged.

The litigation over the \$400,000,000 assessment of coal lands in Schuylkill County, which was regarded as practically settled, was reopened during the week in court by a large number of attorneys representing the county, who told the presiding judge that they were unable to agree with the coal companies and owners on the settlement proposed. Hearings on the whole litigation were therefore asked on behalf of the county. Later an application was made to the court for a mandamus on County Treasurer Hensyl to compel him to proceed with the sale of lands on which the taxes have not been paid for the last two years. Attorneys for the coal companies view the procedure with indifference. They believe the decision of the Supreme Court in the Kemble case of Philadelphia settles all other pending cases. This estate, instead of getting an increase of assessment from \$250 to \$800 an acre, had its assessment lowered to about \$90 an acre on a decision of the Schuylkill County Court, which closely follows the opinion of the Supreme Court.

In connection with the winter meeting of the Coal Mining Institute of America in Pittsburgh, Pa., Dec. 3-5, the members will have the choice of two interesting inspection trips. One is to see the 35-car revolving dumps, the five-mile belt conveyor system in the Colonial mines of the H. C. Frick Coke Co., near Grindstone, Fayette County, Pa.; and the river tippel on the Monongahela River near Fayette City, fed by the above mentioned conveyor system. The other is to observe the rock-dusting system of the Inland Collieries Co. at Indianola, in Allegheny County, in the double Freeport field. This is a very gaseous mine.

Of the 180 fatal accidents in Pennsylvania industrial establishments during October, 69 occurred in the mines, according to the State Bureau of Workmen's Compensation. Forty-seven of the fatalities were reported to the bureau from the transportation companies and 64 from other industrial concerns. Forty of the mine fatalities were in the anthracite district and 29 in the bituminous region. Lackawanna County reported the largest number of fatal accidents in the mines, 15, and Luzerne was second with 14. The deaths by other counties in the hard-coal section were: Carbon, 2; Dauphin, 1; Northumberland, 4, and Schuylkill, 4. The bituminous district fatal report showed: Allegheny, 2; Cambria, 3; Clarion, 2; Fayette, 6; Greene, 1; Indiana, 3; Lawrence, 1; Somerset, 3; Washington, 5, and Westmoreland, 3.

Courtesy Bertha-Consumers Co.

#### Tippel at Rachel Mine

Rear view of top works at Bertha-Consumers operation at Downs, W. Va., in the Fairmont gas-coal field. The mine has its own locomotive for efficient yard shifting.

Directors of the Lehigh & Wilkes-Barre Coal Co., on Nov. 19 declared the regular quarterly dividends of \$3 on the common and 1½ per cent preferred stock and an extra dividend of \$3 on the common stock. Early this year directors declared a stock dividend of 200 per cent payable one share of preferred and one share of common for each share held by stockholders of record March 26. After April 1 last holders of the old capital stock were to exchange their holdings for an equal amount of new common stock. After such conversion and distribution of the stock dividend, shareholders will have received two shares of common and one share of preferred.

C. A. Saunders is now the *Coal Age* circulation representative in the anthracite field. He succeeds Sage Coe, who has been transferred to the Philadelphia district. Mr. Saunders is not new to the coal mining industry, as he has been covering the Nova Scotia field for the last two years.

## TENNESSEE

The Durham Coal & Iron Co., James Building, Chattanooga, has leased several thousand acres of coal land from the Waller interests and will develop the property.

The Glen Mary Coal Co., 227 James Building, Chattanooga, has acquired 1,200 acres of coal land near Glen Mary, and will equip the property for an output of 250 to 500 tons per day. The company probably will purchase a steam shovel mounted on caterpillars, as well as dump cars, rails, etc.

## UTAH

Coal production in Utah for October was 441,789 tons, compared with 535,698 tons in October of last year.

## VIRGINIA

H. M. Fadely, formerly manager at Norfolk for the local County Coal Corporation, is now sales manager for the Dudley Coal Co., with headquarters in Richmond. John W. Bunting, formerly with the C. & O. Coal & Coke Co., and one of the best known men in the trade, is now associated with Dichmann, Wright & Pugh, steamship agents at Norfolk.

## WEST VIRGINIA

The Pond Creek By-Product Colliery, which really is the fuel department of the Norfolk & Western, has eliminated heavy haulage costs by installing an aerial tramway near Williamson which eliminated two bridges, a good deal of track and trestling.

A record for monthly coal production was made in September, 1924, along the Chesapeake & Ohio Ry., the total output being 4,162,665 tons. During the early part of October the movement was equally large, the Logan field contributing 38.5 per cent of the coal loaded in the several fields served by this road. During the first week of October the Logan field shattered all

previous records by loading 1,318 cars daily, a daily output of 65,000 tons. During the second week the average was nearly maintained. Average daily loadings during the first fourteen working days of October amounted to 1,292 cars of fifty tons capacity. In 1902 the C. & O. moved 4,164,260 tons during the entire year.

General Edward O'Toole of the United States Coal & Coke Co., operating in McDowell County, has announced that Gary No. 7 mine will resume at once, giving employment to about 400 men. The mine has been closed down since last June. Other coal operators in McDowell County are optimistic about conditions and expect that in less than 30 days practically all of the mines in the county will be working full time.

The Supreme Court of Appeals of West Virginia, in a decision dealing with the liability of coal companies for injury or death of boys under 16 employed in the mines in violation of the state mining laws has held that "A parent who consents to employment of his child under the age of 16 years in a coal mine is not precluded from recovery as the sole beneficiary if the accident causing the death of the child in the mine is the result of negligence of the employer for which recovery would be had if the employment had been legal." The decision also held that the parent cannot recover if the unlawful employment is the proximate cause of the death of the child.

## WISCONSIN

The Consolidation Coal Co. is attempting to avoid what it considers double taxation on coal stored on the Milwaukee docks of the Great Lakes Coal & Dock Co. It has applied for a writ of certiorari to stay proceedings by the State Tax Commissioner. The company is to pay an occupational tax of \$7,313 under the Wisconsin law and therefore objects to paying \$375,000 of personal property tax on the same coal.

## CANADA

K. A. Blatchford, Mayor of Edmonton, Alta., says that coal from Alberta soon will be making a strong bid for the Pacific Coast bunker trade and that it may be expected to cut into the domestic business of the coast. He asserts that Alberta steam coals compare with the finest on the American continent and that lignites from Edmonton and Drumheller have "run American anthracite out of Alberta and Saskatchewan altogether and have cut the anthracite business of Manitoba to a fraction of what it was." He says that better freight rates, for which Alberta is fighting, is all that is necessary to put the coal of that province in the markets of both the extreme East and West of Canada.

The Dominion Advisory Fuel Committee has issued a further warning on the "continued apathy" of the anthracite-using public in the matter of winter supplies. Imports of hard coal from the United States between Jan. 1 and Sept. 30 were 833,421 tons less than

for the same period last year, and importations from Great Britain are 20,324 tons less. The chief anthracite-consuming provinces are Ontario and Quebec, and in these two provinces alone imports have declined more than 800,000 tons. It is pointed out that the principal mines producing Alberta domestic coal have been shut down since April 1 and are only now resuming production, and even if railway rates were such as to permit any considerable movement of Alberta coal to the East, the needs of the Prairie Provinces would first require to be supplied.

At the District Convention of District No. 26 of the United Mine Workers at Sydney, N. S., on Nov. 17 a motion was introduced to admit delegates from the One Big Union miners of Thorburn and Stellarton, the locals of which recently seceded from the U. M. W. President J. W. McLeod ruled the motion out of order on the ground that the O. B. U. was a dual organization seeking to oust the U. M. W. from control of the district. His ruling was sustained by a vote of 65 to 10.

The Coal Creek Mine, at Fernie, B. C., owned by the Crows Nest Pass Coal Co. which recently resumed operations, is closing down indefinitely. An official statement has been issued giving as a reason "failure to retrieve sufficient business" and advising miners to seek employment elsewhere.

## Association Activities

The West Kentucky Coal Bureau, a traffic organization supported by over 90 per cent of the mines of the western Kentucky field, had a good attendance at a meeting on Nov. 11, at which time two new members were added, and announcement made that a third would come in shortly.

Transportation and traffic matters absorbed the attention of the Smokeless Coal Operators Association of West Virginia at the November meeting in New York. The members were informed that the new all-rail rate of \$2.84 per gross ton from the Pocahontas field to Washington would be come effective on Dec. 8. A special committee was appointed to investigate the possibility of effecting uniform conditions in connection with the demurrage tariff situation at Hampton Roads on the Norfolk & Western, the Chesapeake & Ohio and the Virginian railroads. It has been tentatively agreed to hold the next meeting at Washington on the second Thursday in December. Among those in attendance at the November meeting were R. H. Gross and S. A. Scott, of the New River Coal Co., the former being the president of the association; T. F. Farrell of the Pocahontas Fuel Co.; E. E. White, of the E. E. White Coal Co.; W. D. Ord, of the Empire Coal & Coke Co., and T. S. Crockett, of the Leckie Coal Co.

## New Companies

The Lincoln Coal Co. has been incorporated in Covington, Ky., with a capital stock of \$15,000, by Irvin Davis, H. M. McLain and August Helm.

The Erbest Coal Mining Co., with a capital stock of \$200,000, has been formed at Marion, Ill., by C. I. Hayden, William H. Warder and R. E. Mitchell.

The Line Creek Coal & Land Co., capital stock \$10,000, has been formed at Nelsonville, Ohio, by C. C. Sharp, C. B. Sharp, Fern Parry and others.

The Hill Valley Coal Co. has just been organized, with a view to operating at Julian, in Boone County, W. Va. This company is capitalized at \$25,000 and was incorporated by M. A. Fore and associates.

## Traffic

### Proposed Rate Changes on C. & O. Cancelled by I. C. C.

The Interstate Commerce Commission declined on Nov. 20 to sanction proposed increases and reduction in rates on coal from points on the Gauley branch of the Chesapeake & Ohio, in West Virginia, to various destinations east and west thereof. The schedules have been under suspension since Aug. 25, but according to an order issued by the commission are now cancelled and the entire proceedings dismissed.

### Increase in Rates Suspended

Proposed new schedules increasing the freight rates on bituminous coal from Evansville, Ind., and related points to points on the Chicago & Eastern Illinois Ry. were ordered suspended Nov. 14 by the Interstate Commerce Commission from Nov. 20 until March 20, 1925. The commission will investigate the reasonableness of the proposed new rates.

### Lower Coal Rate for Port Huron

Coal rates affecting Port Huron, Mich., and the river district will be reduced 35c. a ton, effective Dec. 1.

Under the new rates the Pere Marquette will no longer carry coal from Ohio north to Saginaw and then south to Port Huron, as has been done in the past. The new routing will take the cars across the river at Detroit, bring them up through Canada to Sarnia and ferry them across to Port Huron. This means a direct saving in miles carried as well as in rate. The new rate applies to coal billed for Marysville, St. Clair, Marine City, Armada, Washington, Chesterfield, New Haven, Richmond and Smith Creek.

Roads carrying directly to Port Huron which will operate under the new rate are the Grand Trunk, Pere Marquette and Detroit-Toledo Shore Line.

It was estimated by officials of the Pere Marquette that \$175,000 would be saved local industries during the first year of the rate reduction.

### Not to Reopen Western Rate Case

The Interstate Commerce Commission declined on Nov. 10 to reopen for further argument the case involving new Western coal rates. Petitions for a re-argument of the case were filed by the Public Service Commission of Wyoming, the Rock Springs-Kemmerer operators and others. The I. C. C. held that the rates it had fixed on coal from Colorado producing fields to points in northeastern Colorado are just and not discriminatory.

## Industrial Notes

Alfred G. Norris has been appointed manager of the New England office of the Strom Ball Bearing Mfg. Co., with offices at 75 Pearl St., Hartford, Conn. He has been identified with the ball-bearing industry for a number of years and is well known among industrial engineers and manufacturers in the New England States.

A. W. Wiese, sales engineer, has been transferred from the Philadelphia office to the Hartford office.

The Tri-State Engineering & Construction Co. has just taken over the contracting business of C. I. Keck, of Morgantown, W. Va., after having been organized as a result of the consolidation of the T. R. Marshall Engineering Co.; Baritell Brothers, engineers, of Morgantown; McCutcheon Engineering Co.; R. A. McCall Construction Co.; and J. E. Falter, construction engineer. The new company, of which T. R. Marshall is president, is capitalized at \$50,000. It will project its work into all sections of the West Virginia, Ohio and Pennsylvania fields. Mr. Marshall's company has been specializing in mining and coke-plant construction.

Conveyors Corporation of America, Chicago, Ill., announces the appointment of Frederick E. Bausch, 1105 Chemical Building, St. Louis, Mo., as district representative of eastern Missouri and southern Illinois.

The stockholders of Joseph T. Ryerson & Son, Inc., Chicago, have purchased a substantial interest in the Reed-Smith Co., Milwaukee. The Reed-Smith Co. is an independent steel warehousing company serving the industry in that section of the country. Under the new plan the officers of the Reed-Smith Co. are D. M. Ryerson, president; George W. Smith, vice-president and general manager; E. L. Hartig, treasurer, and Carl Gallauer, secretary. Joseph T. Ryerson & Son is the largest independent steel warehousing organization in the country, operating plants at Chicago, St. Louis, Cincinnati, Detroit, Buffalo and New York. A complete range of steel products, including bars, shapes, plates, sheets, tubes, rivets, bolts, nuts, etc., is maintained at all six plants.

## Obituary

George W. McNeil, president of the Grand Junction Mining & Fuel Co., general manager of the McNeil Coal Co., and secretary of the Cameo Mercantile Co., died Nov. 4th at St. Joseph's hospital in Denver following an operation. He was buried the following Saturday. In his death Colorado loses one of its most progressive mining men.

James Wood, well known in the coal industry of central Pennsylvania, died at his home in Punxsutawney, Pa., on Nov. 17, aged 82. He had been connected with the Berwind-White company over 40 years. He had been a miner in England and came from there in 1868. He leaves a daughter and four sons.

George S. Blewitt, aged 50 years, purchasing agent for the Vinton Colliery Company for the past 31 years and one of the most prominent residents of Vintondale, Cambria County, Pa., died suddenly at his home on Tuesday morning, Nov. 18. He is survived by his widow and two sons. He was prominent in Masonic circles and was Justice of the Peace in Vintondale.

## Coming Meetings

**National Exposition of Power and Mechanical Engineering.** Annual exposition, Dec. 1-6, Grand Central Palace, New York City. C. F. Roth, Grand Central Palace, New York City.

**American Society of Mechanical Engineers.** Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**West Virginia Coal Mining Institute.** Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**Coal Mining Institute of America.** Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

**West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers.** Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

**American Institute of Mining and Metallurgical Engineers.** Annual meeting, Feb. 16-19, 1925, 29 West 39th St., New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Midwinter convention, Feb. 9-13, 1925, 29 West 39th St., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Switch With Each Part Set On Separate Base

Most electrical men who have had maintenance experience around plants where the common type of knife switch is used are familiar with the necessity of having to remove the entire switch when perhaps just one of the blade or fuse contacts is burned and needs replacing. The Square D Co., of Detroit, Mich., has developed a line of indus-

### Switch Without Slate Base

The individual insulating bases are mounted on a metallic back. The copper connectors, carrying clips and lugs, are easily renewed. The switch pictured has protectors on the line contacts.

trial safety switches on which contact renewals can be made in a short time and at small cost.

Instead of the switch being mounted on the customary slate base, it is mounted on metal and each part insulated from the metal by a small piece of molded insulating material.

This individual base construction makes it possible to remove any part from the front of the switch in a few minutes without disturbing the wiring. It is unnecessary to remove the base from the switch box. The copper connector has fastened to it a jaw at one end and a solder lug at the other. Both are held by means of bolts with the heads in a downward position. The bolts are kept from turning by fitting the heads into grooves in the separate bases. The connector is fastened to the individual base by a screw which threads into a brass socket molded in the insulation. The removal of this single screw permits quick replacement of the switch jaw, connector or solder lug.

It is claimed that the molded insulating material of the individual bases is tough and will not break or crack, also that there are other advantages in not using slate. The switch weight is reduced about 25 per cent and the possibility of short-circuits in the metallic streaks, which sometimes occur in slate, is eliminated.

Another interesting feature is the provision of porcelain protective covers for the line contacts where the operating conditions warrant this precaution. When a switch is in the "off" position the only live parts are the line contacts. By having these protected it is only through intentional effort that a person, who may open the switch box, can make contact with live parts. The individual porcelain covers can be easily attached or removed without disturbing the rest of the switch.

### Idlers with Anti-Friction Bearings Save Power

The Stearns Conveyor Co., of Cleveland, has put into service their new special belt conveyor idler, equipped with Timken roller bearings. The device is being used with their complete installations of material handling equipment,

**Dirt and Dust Cannot Get Into Bearings**

Grease under high pressure is introduced to the bearings. Old grease is forced out and it acts as a seal against dirt or dust.

but they are also designed to make possible their use to replace any type of carrier now installed.

The pulley shells, made of No. 10 gage pressed steel, drawn together with rod bolts, are practically indestructible. The through pulley shafts are fitted with roller bearings, of the same size as used on the front axles of Ford automobiles. The generous size of this bearing allows a large factor of safety but when wear does begin, it easily can be compensated by means of the adjusting nut at one end of the shaft without

**If Idlers Run Freely Small Motor May Be Used**

The rollers run so freely that the conveyor requires but little power to drive it. Inclined conveyors are much cheaper than old types because of the reduced investment in the driving motor.

removing the pulley from the carrier.

The bearings are carried in heavy steel tubes inside the pulley shell. These tubes also serve as a reservoir for grease. One of the outstanding features of the carriers is the method of applying high-pressure lubrication. Grease applied to the high-pressure fitting on the end of the shaft enters the grease reservoir near the center of the pulley, forcing the worn-out grease from the bearing out through the labyrinth washers. The grease seal thus formed prevents any dust or grit from entering the bearing. These pulleys require greasing not more than once or twice a year, and to do so, it is not necessary to remove the pulley from the carrier.

### Small Centrifugal Pump as Efficient as Large Ones

A new low-head pump has recently been developed by the Allis-Chalmers Manufacturing Co. This new pumping unit is similar to the present type S design which has long been one of the standard types manufactured by the company. The new pump will be built in small sizes, and most of the details will be similar to those of larger units, except that a number of mechanical improvements will be incorporated. The efficiency of the pump has been raised by several important changes which reduce the hydraulic losses.

The cross-sectional view of the pump shows a few of the new features. The bronze companion wearing rings are L shaped to reduce disturbances in suction passages and thus increase the efficiency. Split bronze inclosed glands are provided with drains to prevent water from being thrown off revolving

**Small But Efficient Pump**

This new unit has all the features that go to make up a high-efficiency, large-size centrifugal pump.

parts and entering the oil-lubricated bearings. The stuffing box throat is provided with bronze bushings which can easily be removed and replaced. The shaft is made of annealed steel and is provided with removable cast-bronze sleeves which extend from the runner hub to the inside of the bearing housing.

The outboard bearing is the double-acting type. It is firmly fixed and locked in position so that it cannot become loose. Thrust is taken in either direction, and a center collar is provided. The oil bearings are split and provided with two oil rings. Oil is led to the center of the bearing and it is thus completely lubricated over its entire length. All oil-hole covers are self-closing, thus keeping out dirt. Oil-level indicator cups are supplied with each bearing. The water seal passages are

**Operating Characteristics Prove Important Facts**

The curves of this 5-in. centrifugal pump show that it can deliver 900 gal. per minute against a 68 ft. head at an efficiency of 80 per cent.

integral with the upper half of the casing and can be arranged for outside seal whenever necessary.

The shaft nuts are unusual in that they are designed to act as oil throwers to prevent oil from creeping along the shaft, and also to prevent any water from entering the bearings. The characteristic curves of the pump show its performance under various conditions.

### An Across-the-Line Starter

A push button starter for squirrel-cage motors up to 25 hp., 220 volts or 35 hp., 440 to 550 volts and self-starting polyphase motors up to 50 hp., has recently been developed by the Allen-Bradley Co., Milwaukee. It is equipped with inverse time limit overload relays, no-voltage release, push button station and copper-to-copper rolling contacts. It is also inclosed in a steel cabinet and operated entirely from a push button station with a start and stop button.

Relatively small induction motors on large power lines do not create serious line surges because the initial inrush current is only a small percentage of the capacity of the line. It is not generally recognized that the induction motor has inherent characteristics which prevent it from drawing more than a limited amount of current under the most severe starting conditions. The transformer action between the two windings of the motor exerts a demagnetizing action when the current has reached a certain value.

**Protective Starter**

Small motors do not ordinarily cause serious line surges yet some kind of switching device is always necessary to protect the equipment.

## How About Another Club?

**C**HRISTMAS and vacation clubs have enabled people of impecunious habits to finance their Christmas giving and their yearly trips to the country. The two kinds of provision for the future balance one another admirably. The banks have Christmas money coming in midsummer when they are meeting the drain of the vacation payments, and vice-versa.

How about coal clubs with payments ranging through the year and maturing when coal can be purchased most cheaply and with the greatest assurance of delivery? It certainly should please the coal operator and afford the consumer cheap and cleaner coal, assured delivery and the least strain on his pocketbook.

After all why not? The cost of coal is greater than that of the Christmas giving and but little less than the high cost of vacationing. More power to the scheme if it can be achieved! Insurance in all forms is popular. Why not insure a full coal bin and avoid winter worry? Even the apartment-house owner and factory manager might favor it. And the banks would be benefitted, for it would smooth out their load curve by making three periods of maturity instead of one or two. It would leave more money in their hands at each period of maturity.

## Ready to Your Hand

**P**LANT publications are expensive, especially if of frequent issuance, and on looking them over one sometimes wonders whether the miners' circulars of the Bureau of Mines would not be a fair substitute for them or at least a valuable supplement to them. One of the leading themes of the plant paper should be safety, and this feature the Bureau of Mines' miners' circulars teach to perfection, better perhaps than an article from the general manager or his superintendents.

In many cases these publications cannot be obtained without charge, the free list being already exhausted, but they can be purchased at a low price from the Superintendent of Documents at Washington.

If, however, the plant publication is provided why not in preparing it draw freely from Bureau of Mines' publications, leaving out parts which might not relate to workings such as yours and giving due credit for the material taken. The Bureau is anxious to have an opportunity like this to do the industry a service.

The work of the Bureau is hampered by inadequate distribution of its pamphlets. It is waiting to aid in safety work if an opportunity only be given. Mining men would seem to have overlooked what an advantage the publication of these elementary monographs confers on them. Mine superintendents and managers should have most of the Bureau's publications—certainly all those relating to safety—and should make it a point to see that all responsible men in the organization

not only receive or purchase them but read them as soon as they are available. They should be seen in every mining man's library.

## Get Together Electrically

**W**ITH consolidations of companies the whole question of the efficiency of the private power plant is revived. A group of adjacent mines can build and operate a power plant much more economically than a number of individual mines could maintain one at each opening. The new plant built for them all can be of the most modern type. It is true it will not be able to avail itself of an advantage which each of the others might have taken but usually did not, for it cannot use the refuse coal of all the mines, though it can use the refuse from one or two and so economize where the others failed.

So many economies go with an adequate plant that each new consolidation should be followed by a careful inquiry as to the advantage of manufacturing power at one or more of the mines thus consolidated. The diversity factor of many mines probably will be better than that of any one of the mines in the group. A get-together financially should be followed by a get-together electrically.

An article in this issue shows how a company buying power combined its loads in metering them and saved 19 per cent in its power bill. This shows how having a plant for several mines will smooth out the load curve and make the operation of the power plant for a group of mines more economical.

## How Many Sub-Bosses Have You?

**A**DEQUATE supervision is the secret of success. Neither tonnage nor economy can be obtained without it. Even if every man on the job were keyed up to do his best he could not do it if there were no correlation of effort. Nowhere is a man more helpless than in the mines unless he is given a proper degree of co-operation from the forces outside. But, as men rarely exert their best efforts, still more do they need to be under supervision.

The tracklayers, bratticemen and roadmen can usually make a pretense of energy without achieving anything. There are lots of plausible excuses for idleness—waiting for boards or props, for some one to square a room neck, for water to be removed, for the smoke to drift away, for rock to be loaded, for trips to be pulled, for spikes or rail to arrive. When such men delay their work they hold back other men. Often they have made up their minds to follow a set plan, and a little interference at one place holds up their efforts, when if they would work where opportunity presented they could fill in almost every idle moment. Some men

have an irritability that prevents them from regulating their work to circumstance. So they need to have the guidance of a boss.

Give the mine foreman plenty of help. Put the men holding subordinate positions definitely under the mine foreman, hold him responsible for their work, and he will get results. Men who on the surface would not be permitted to work without supervision are often put to work underground in the dark without a boss. The reason is simple. We all know how men idle when working above ground, but we do not know how often men dilly dally below ground, or how often they go to sleep on an overcast or in a return entry when they ought to be working. We all know how men find excuses for idleness in the open air. There are more excuses in the mine, yet we allow the men who find them to idle on the job without observation. Supervision is not money thrown away, it is money well invested. Many a mine fails to get out cheap coal because all the supervision is left to one mine foreman.

### Fear and Fatality

**S**AFETY MEN, showing us how accidents can happen, are beginning to hedge a little and to question whether the psychology of fear may not produce the very dangers against which they have been warning. It cannot be gainsaid that fear sometimes is a cause of accident. The animal or the man attacked by a savage beast is likely to be palsied by fear and unable to run or even feign death. The man who will walk along a plank laid on the ground without a tremor will quite generally fail entirely to walk that plank if laid between two windows on the fourth story of a building.

An automobilist whose engine stops on a railroad track may fail utterly to use the same judgment that he would summon to his aid if his engine stalled at the side of the curb. Locked in a hotel room by a key which he himself has turned on his own side of the door, a man may fumble and burn to death before he can turn the key if the house catches on fire. Fear masters him. His judgment no longer controls his body.

The same may be true of a miner. His dread of a roof fall may make him unable to run; his fear of death from the afterdamp of an explosion may enfeeble his body and destroy his judgment. In fact the apprehension of death often causes a man to interpose but a feeble resistance to disease when it attacks him.

Perhaps there are dangers against which we may battle best if our minds have not been prepared beforehand to anticipate and dread them. It may be that in regard to some accidents the less we dwell on them the better we shall meet them when they confront us. We need regarding these to think less about the result and more about prevention, lest when they confront us we may be enfeebled to combat them rather than instructed how to avoid them. Our instinct then may serve us better than education.

But fear, if not too abject, often is our best counselor to safe action. Many of us, in strange circumstances, would be disposed to take risks if not duly counselled by discomfiting anticipations, and in a campaign against accident we would do well to remember that there is a safe and unsafe measure of fear. There are premonitions which spur us to caution. There are fears which unnerve. The passenger on a boat in a stormy sea often is made helpless whereas the seaman on that same boat is moved only to take further precautions. He even accepts certain risks that

he may avoid greater dangers to himself and his associates.

In the safety campaign gruesome posters frequently are undesirable because they stress danger rather than precaution. They may cause more harm than they cure. They may help some men, and they may harm others. Our reactions are quite dissimilar, and the poster that will serve with some a useful purpose may not be uniformly helpful. It is sometimes a matter of balance whether a poster or other warning will, in the main, be helpful or harmful. Timorous persons may be merely scared by them. Bolder men may be counselled to take measures of prevention. Still more fearless men may take them as a "dare" and as an opportunity to obtain a thrill that appeals to their adventurous souls.

However, men exposed to dangers cannot well avoid realizing the results of accident, and consequently perhaps our gruesome posters will not scare them at all. But if posters do not make men think, they serve no purpose whatever. Consequently it would seem better to use posters that deal with preventive methods rather than with terrifying outcomes, though there are eventualities of a more remote character that we can portray such as poverty in the home, widowhood and orphanhood that do not introduce the fear complex.

### Right to be Heard

**A**FTER years of neglect, electrical engineers are being asked to give their views as to power savings. Time was when the big boss refused to listen to them, and they learned to be silent and discreet. When they pleaded their case it was met with a shrug of the shoulders and other visible signs of impatience, but the external pressure of power bills has brought even the big boss to a realization that the right kind of electrical engineer can be of considerable assistance in lowering his costs.

Many are the ways in which electrical engineers can save money for their companies, and successful is that electrical expert who is ready with suggestions when they are sought. The superintendent who does not listen is slated for replacement. If he adapts himself to the suggestions of the electrical engineer he will better his standing with the company for there is much that the electrical engineer can tell him as to economy. He can lower his line losses by the use of substations near the load, by providing adequate conductors and by better bonding. The same provisions will assure him of more adequate power for operation, decreased depreciation of equipment and fewer burnouts.

By the introduction of automatic substations he can reduce labor costs. By distributing loads he can cut down his power cost and he can avoid the purchase of much unnecessary machinery for his generating station, should he have one. By correcting his power factor if he uses alternating current he can increase the carrying capacity of his conductors without a heavy bill for copper. By the same means also he can make better use of the power he is generating or purchasing. By better bits he can lessen his cutting costs and avoid burnouts and deterioration.

Consequently it will pay him to have his electrical engineer at the Huntington meeting of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers where he can get in touch with new developments, most of which relate to power saving.

## Rock Dust No Cure-All, Say Western Engineers

Coal Fields That Introduced Dusting in America in 1911  
Today Consider Water Also Essential—High-  
Pressure Dusting Wins Favor—Mud-  
Spraying Experiments Progressing

BY E. W. DAVIDSON AND ALPHONSE F. BROSKY  
Editorial Staff, *Coal Age*

**R**OCK DUSTING is no cure-all for the explosive ills of coal mining. It is necessary in most mines, but no mine can be rendered safe against the explosibility of coal dust by the use of pulverized rock alone. Water, judiciously and persistently applied is just as necessary.

This is the conclusion of the West—the coal mining region in which rock dusting was introduced to America. The West ambitiously is dusting today, in an effort to live up to the expectations that every mine in the mountains be dusted before winter. Fifty miles of entry are already dusted. The West is distributing dust by traveling blowers in large volume at low pressure and in small volume at high pressure. It is discharging dust into intake airways. It is spreading dry adobe by hand and by machine and is getting several distributions from each application by stirring up the floor layer occasionally. It is using ground limestone, leucite,\* gypsum and shale. It is spraying dust in the form of mud. It is trying literally every method of "dusting" known—and some that are unknown. And in addition to that it is using water liberally in regions where water is available.

There have been many object lessons in the Rockies during the past three years of the horrible loss and suffering caused in mines that are not dusted. Furthermore, in September there was an object lesson offered by the Rains mine of the Carbon Fuel Co. in which an explosion killed five men but was markedly reduced in force and finally checked entirely by rock-dusted areas.

In view of all this experience, the West may know what it is talking about when it says rock dust is no cure-all, but that dust and water together come near attaining that distinction. Its judgment is based on practice.

There really is little that is novel in 1924 about the dust blower and the dust trough barrier now used in a handful of mines in southern Illinois, in one mine of western Kentucky and in a scattered few in West Virginia and Pennsylvania. Both were used in Colorado

in 1911, and Wyoming saw some dusting in that same year.

The earliest protective dusting in this country was at the Delagua mine of the Victor American Fuel Co., in southern Colorado. That company was inspired by rock-dusting experiments in England. Capt. Jack Smith, safety engineer for the Union Pacific Coal Co. at Rock Springs, Wyo., recounts that "an English operator at Altofts, Eng., as early as 1906 noticed that natural shale or inert dust checked the propagation of an explosion in his colliery."

The dusting at Delagua began in 1911 soon after a series of coal dust explosions including one at that mine. Such men as W. J. Murray, then general manager of the company and B. W. Snodgrass, then boss of Delagua, but now general superintendent, decided that adobe dust from the countryside was sufficiently inert to be used in the place of rock dust and certainly was fine enough when thoroughly dried by the sun. So they sent men out on the wagon roads in dry periods to haul large volumes of the road dust into protected storage.†

The first application of dust in the mine was made by men who carried dust in large buckets and threw it on the roof, ribs and timbers with small domestic coal shovels. The dust was thrown against the ribs, etc., with enough force to dislodge the accumulated coal dust and replace it with adobe dust. In that manner the timbers, small ledges, crevices, and other lodging places for dust were loaded up to the angle of repose with inert dust, leaving less room for the lodgment of coal dust.

Then along the same roads, shelves were placed one above the other on the ribs by drilling holes in the coal in which pegs were driven which supported the shelving. These shelves were loaded with as much adobe dust as would stay on them. At all points where height would permit, shelves were suspended to timbers with wire and loaded up with adobe dust; and at points where the roof was unusually high, V-shaped troughs filled with adobe dust were set at right angles to the entry on timbers and supported so that they could easily be overturned.

While this application was being made, a blower was constructed to blow adobe dust into suspension. Sev-

\*Way back in 1911 the machine illustrated in the headpiece was built and put into operation at the Delagua mine of the Victor-American Fuel Co. in southern Colorado. The idea came to B. W. Snodgrass, now general superintendent for the company, from England, where dusting was evolved experimentally in 1906. This machine blew adobe dust through the Delagua mine for three or four years. The dust was not ground, but merely shoveled up from the roads in dry weather and stored under cover.

\*Leucite is a rock-forming mineral composed of potassium and aluminum metasilicate.

†See "Prevention of Coal Dust Explosions, Vol. 2, p. 756, Nov. 3, 1912, and "The Explosion at Ravenswood," Vol. 5, p. 411, Mar. 7, 1914, in *Coal Age*. Both articles are by Samuel Dean.

eral types of blowers were constructed before one of practical value was perfected. The practice was to load up the hopper of this blower; then load two pit cars with adobe dust in sacks and send this train into the mine propelled by an electric locomotive. Two men went with it—one to operate the locomotive and the other to operate the blower. This blower was put in operation and hauled by the locomotive against the air current until all the dust had been blown away. The dust was blown against the ribs and roof where some of it naturally lodged immediately; some was carried long distances by the air current and, of course, much of it found lodgment on the floor.

A film of coal dust would accumulate on top of the adobe dust, especially on the shelves and timbers, and men were sent along the roads periodically to scrape off that film of coal dust and to pile on more adobe dust.

They found that by short circuiting the air on certain cross entries where the locomotive could not go, the air current would carry the adobe dust long distances and deposit a film of it on the roof, ribs and floor of rooms as well as the entries.

The Delagua mine was dusted with adobe systematic-

ally in Wyoming, now the property of the Union Pacific Coal Co. Superintendent Redshaw, in charge at the time, had the dust spread thickly on all entries so that it would mix with coal dust under the disturbance of travel. This was done because the extreme dryness of the region made sprinkling practically out of the question. Water for domestic purposes had to be hauled to Winton in tank cars. Although that was more than six years ago much of the original adobe dust is still noticeable along the ribs of the entries.

A chronology of early dusting in this country would record the next use of "rock dust" in the Allison No. 1 mine on the Monongahela River in Pennsylvania. According to H. I. Smith, chief mining supervisor for the U. S. Bureau of Mines, a few miners in 1914, on their own initiative began an interesting practice.

In front of each face to be shot they placed two carpenters' horses or other supports approximately 30 in. high. On these they rested a wide plank or platform heaped high with fine motor sand. The force of the shot blew this loose sand back toward the room neck and disseminated it freely but did not mix it with the coal to be loaded out. A charge of motor sand thus

#### Reliance Mine

One of the first to use adobe dust in America. It was dusted in 1911 and, even today though twelve years have elapsed, there is evidence in the manway of the mine of that early rock dusting.

cally and effectively until 1918 when the large supply of dust which had been stored in the previous year had been exhausted. After that the company relied upon sprinkling with water for protection against the coal-dust hazard. Now, however, systematic dusting has been readopted at the Delagua mine, and a dust-grinding plant is being installed. A new blower is in process of development.

In 1911, soon after dusting began at Delagua, the Reliance mine at Rock Springs, Wyo., then in process of construction, was dusted with adobe. George B. Pryde, vice-president and general manager of the Union Pacific Coal Co., says of this pioneering:

"When the slope, air course and manway had reached a distance of about 1,000 ft., adobe dust was scattered in the manway for a distance of about 600 ft. to a depth of about 8 in., it being the idea that as men and animals walked into the mine they would pick up this dry adobe dust and it would be carried in along the entry and deposited on the ribs.

"After a period of twelve years some of this adobe still remains in the manway. The ribs of the manway are heavily coated with this dust, and adobe is still noticeable along the ribs of some of the entries. This first attempt at rock dusting by The Union Pacific Coal Co. was inexpensive and fulfilled expectations."

Though dusting was discontinued at Reliance at about the entrance of the United States into the World War in 1917, another job of rock dusting was done in that same year when the Megeath Coal Co. made one general distribution of adobe dust through the Winton

was distributed with each 6-ft. advance in the territory worked by these men. The practice was continued for a year or so.

The next year—1915—the Pittsburgh Coal Co. experimentally dusted 2,000 ft. of entry in one of its mines with pulverized limestone but this proved to be merely a sporadic effort.

Soon after this exhaustive experiments in the use of finely divided shale began at the mines of the Old Ben Coal Corporation in southern Illinois. There, the greater part of the intensive development of dusting that has been carried on by coal companies was made. But not a single mine in southern Illinois followed the lead of J. E. Jones, Old Ben safety engineer, until a little over a year ago when the Burlington railroad, at its Valier mine nearby began intensive dusting along the lines laid down by Jones and the U. S. Bureau of Mines. Recently, the Chicago, Wilmington & Franklin Coal Co. has borrowed the Old Ben distributor and has dusted parts of its Orient mines, and one or two other large Illinois companies declare they will dust as soon as they find an efficient distributing unit. But the number is few.

The West Kentucky Coal Co., with twenty-two mines in its end of the state, has just installed an impact pulverizer and is crushing shale taken from above the No. 12 seam of coal. The company is dusting entries but not rooms in one of its mines, using V-trough barriers in all aircourses just outside the live workings.

A distributor has been built, under the eye of T. E. Jenkins, operating vice-president. It is a steel hopper

#### Cement Mortar Smooths Away Dust Lodgments

This main entry in Mine No. 6 of the Phelps Dodge Corporation has the ribs, roof and timbers treated with mortar by the cement gun. Although coal dust can accumulate it is given greatly reduced opportunity for lodgment when the angles are rounded by a cement mortar coat.

car with a screw feed driven through a speed reducer by a belt from the shaft which operates a blower. A 5-hp. motor supplies power. The stream of rock dust is directed by a man seated on the rear end of the car who handles a canvas discharge hose.

In the east the Indianola mine of the Inland Collieries Co., a short distance from Pittsburgh, under its general manager, T. G. Fear, was probably the first mine to adopt the practice of rock dusting on a large scale. It has completely dusted all the entries in the mine, which is a large one producing 3,000 to 3,500 tons per day. All the dust laid in this mine has been purchased, but a pulverizing plant having a capacity of about one ton per hour is in process of construction.

Several years ago, long before any notice was given generally to the merits of rock dusting, William Hulings, superintendent of the Gallatin mine of the Pittsburgh Coal Co., experimented with a rock-dust distributor. Evidence of the work of this machine was seen on the ribs along a stretch of entry in the Gallatin mine until it was covered by a more recent application of rock dust.

The Pittsburgh Coal Co. is working energetically in the rock dusting of its mines, all of which eventually are to be treated. About 10 carloads of rock dust have been shipped to this company, more than half of it already has been applied. Six of its mines have this work in various stages of completion, and rock dusting was started recently in the seventh, the Mansfield mine. Prepared limestone dust is being used. The company has been working on several types of distributing cars. One type which will likely be adopted as standard is equipped with a stationary nozzle. Mining men inside and outside the company are highly impressed with the machine. The company has gone a step farther than any other, to our knowledge, by building a special locomotive for rock dusting purposes, possessing the proper speed characteristics and other details best-suited to the needs of this work.

All the haulage roads (13 miles) in the comparatively newly developed Harmarville mine of the Consumers Mining Co., near Pittsburgh, have been covered with prepared limestone dust, applied by a distributor which this company has been developing. The dusting of aircourses is next on the company's program in this mine, and this work has been started.

In the Coverdale mine of the Pittsburgh Terminal Coal Co. rock dusting has become one of the standard mining practices. About six miles of haulage roads have been dusted by machine thus far; twelve miles of

haulage road and all the aircourses remain to be dusted. Prepared limestone dust, some coming from Ohio and some from Michigan, with 80 per cent fine enough to pass a 200-mesh screen is being used. In this mine a study of methods is being made by Research Fellow C. H. Dodge of the U. S. Bureau of Mines and the Carnegie Institute of Technology. This fellowship was instituted and financed early this year by the generous aid of interested parties.

The Hillman Coal & Coke Co. is laying prepared limestone dust by machine in two of its mines and will follow out a similar program in them all. One of the two mines of the Republic Collieries Co. at Russelton, Pa., is being dusted; the other is closed down. The Ontario Gas Coal Co. and the Lincoln Gas Coal Co. have just started in this work. The Springdale mine of the West Penn Power Co. is being rock dusted, and plans are being laid for this same treatment of the coal dust in its Beech Bottom mine in West Virginia.

In Washington County the Langeloth Coal Co. is preparing to rock dust. The Vesta Coal Co., the National Mining Co. and the Bethlehem Mines Corporation are investigating methods of rock dusting and the equipment required. Westmoreland County is represented by the Westmoreland Coal Co., which has been laying prepared limestone dust by a machine of its own make and by hand.

In Fayette County, where the need for rock dusting is about as great as in any locality in the country, little activity is noticeable. The Oliver & Snyder Steel Co. is one of the few companies in this county that are distributing rock dust. In Greene County the Nema-colin mine of the Buckeye Coal Co. and the Mather mine of Pickands-Mather & Co. have done much dusting by hand. They will use machines in the near future.

Only three companies, we believe, are rock dusting in Cambria County. One of these is the Berwind-White Coal Mining Co. which has developed a machine and is now engaged in rock dusting two of its mines; another is Peale, Peacock & Kerr, Inc., which also is installing a pulverizing plant, and the third is the Penelec Coal Corporation which has started to rock dust its five mines. The Pennsylvania Coal Corporation has been rock-dusting some of its mines by hand, but the work is still in an experimental stage. The company is disposed to favor the use of rock dust barriers.

As for the other eastern states, little can be said except that they are surprisingly slow in taking advantage of the merits of rock dusting. Ohio operators apparently have given this matter no consideration.

#### Mill Tailings Applied by Cement Gun

Ribs and roof are partly coated with mill tailings applied with the cement gun and partly uncoated. The difference between the two can be clearly seen.

**Rock Dusting Machine at Old Ben**

This machine at the Old Ben Coal Corporation's plant, West Frankfort, Ill., has done such good work in Old Ben that it recently has been sent to the Chicago, Wilmington & Franklin Co. to do an equally beneficent work in its mines.

West Virginia is slow, particularly the non-union fields. The Consolidation Coal Co. is said to be developing rock-dusting equipment. It and one or two others save the state of West Virginia from being listed with Ohio. Robert Lambie, chief of the department of mines of West Virginia will probably present for enactment new laws before the next state legislature compelling rock dusting of all mines in this state.

Kentucky also is backward. The West Kentucky Coal Co., however, is installing a pulverizer and is rock dusting. Few other mines are following its footsteps. Neither Virginia nor Maryland have displayed active interest in the undertaking. Tennessee is doing little rock dusting. In Alabama many of the companies so far appear content to spend as much as 10c. per ton for wetting down coal dust (if this is possible) rather than save by rock dusting about 9c. of that cost. However, not all the Alabama mine owners have overlooked rock dusting. The Sloss-Sheffield Steel & Iron Co. is going into the work in a big way. It is installing a pulverizing plant. The Gulf States Steel Co. and the De Bardeleben Coal Corporation are beginning to rock dust and the Tennessee Coal, Iron & R.R. Co. has made designs for a rock-dusting car.

Limestone is being used almost universally in the East. The mine owners do not consider the use of any dark-colored rock dust good practice. They have discovered that powdered limestone dust is almost white and therefore reflects light much more efficiently and affords better illumination than gray shale dust.

Frank Haas, consulting engineer of the Consolidation Coal Co., suggests an investigation of the merits of the hydrous silicate of magnesium, steatite, more commonly known as soapstone or talc. In some deposits this rock is only one-third to one-half as hard as limestone and possesses approximately the same specific gravity. It is also extremely white. Extensive deposits are found in New York and in many coal-producing states. At present it is used chiefly in the manufacture of paper and composition roofing.

Many rock-dust distributors are being developed in the eastern mines but few have reached such a stage of operation as would warrant their being termed entirely successful.

As far as Canada is concerned we hear that rock dusting has been commenced by the Dominion Coal Co., and so far is confined to the main electric trolley road in No. 1B mine. The roof of the roadway is supported on steel girders and lined with concrete to prevent spalling. The road which is ballasted with slag is two miles long. The dusting has been done with powdered dolomite rock, 80 per cent of which will pass

through a 200-mesh screen. The first application was made by hand on the roof, sides and floor, the flanges of the girders all being filled. Five pounds per square yard were placed on the floor and 3 lb. on the roof girders. The incombustible material in the floor dust is not allowed to fall below 75 per cent. A second application has been made with the cement gun on sides and roof and on the floor except at crossings which are hand-dusted. Shelves containing one ton of dust are placed at 600-ft. intervals, and the mine is divided into panels, the entrances and exits of which are dusted for 400 ft. in the same manner as the main roadway. Compressed-air power is used in the workings exclusively.

These Midwest and Eastern dusting enterprises, no matter how efficiently performed, do not convince the Western mining engineer of their efficacy where the mines are dry. It is the excessive dryness of the high altitudes which moves him to say that dusting alone is not sufficient protection against coal-dust dangers. Western engineers believe, with Dan Harrington, once a Bureau of Mines' engineer but now a consulting engineer in Salt Lake City, that precautions must be taken at the face to prevent the formation of coal dust and its dissemination by air currents.

"If we don't have that," declares Harrington, "the rock-dusted mines of this country are liable to suffer some severe jolts in the future, just as our sprinkled mines have been jolted in the past, due to slipshod methods and overconfidence in the efficacy of water."

The West has had some coal dust lessons that are still fresh in mind. It knows that dust on an intake airway which started a fearful explosion less than two years ago was 65 per cent inert—a percentage that rock-dust authorities generally consider will make the coal dust innocuous. This dust bred the explosion partly because it was extremely dry—2 per cent moisture by analysis—and because of its fineness. A large percentage of a sample taken at the point of the blast's inception passed through a 325-mesh screen. Dust such as this, which was mostly air settleings on timber caps and the like, was borne there by the air stream because it was not rendered harmless at the faces.

In western mines to make the dust moist is an important part of the program. The best examples of this effort are at the Stag Canyon mines of the Phelps Dodge Corporation, Dawson, N. M., but in several other Utah mines consistent sprinkling is required.

The usual practice is to lay 3-in. water lines in all main entries. In panel entries 1½-in. pipe lines carry water to points within 100 ft. of the faces. In rooms

**Earliest Dust Blower Design Not Unlike Models of Today**

This device, which was built in 1911 at the Delagua mine in Colorado consisted of a steel hopper to carry the dry adobe dust and a 3-hp. blower to force a stream of air through a pipe receiving the dust by gravity from the bin. A locomotive, two cars of dust in bags and this blower car comprised the trip which introduced the practice of dusting into the coal mines of this country.

$\frac{3}{4}$ -in. lines are maintained 20 or 30 ft. from the faces. On all entries hose connections are provided every 100 ft. for periodic sprinkling by hand and at room faces where the greatest emphasis is placed upon sprinkling, every loaded car is to be sprinkled by hose and each mining-machine cutterbar is equipped with a  $\frac{3}{4}$ -in. pipe, reduced at the end and bent down pointing directly on the chain, to saturate every ounce of bug dust that is made. These provisions with sprays for all loaded trips at main partings and various systems of atomizers and exhaust steam nozzles on intake entries are now being put in operation by western companies who regard them as important adjuncts to the distribution of inert matter through the mines.

In the practice of dusting, adobe has been lavishly used in most Rocky Mountain mines, especially those of the southern districts where that sort of dirt is obtainable almost anywhere around the mouth of the mine by the simple process of shoveling it into mine cars. It is spread through entries by hand shovel. Later it is stirred up by occasionally dragging the top of a pine tree through the roadways behind a trip. The extreme fineness and lightness of adobe dust when it is dry causes it to be easily stirred up and transported long distances in the air. One man for every 6,000 ft. of entry can keep this adobe raked loose and the coarse coal cleaned out of it. When the proportion of coal to adobe becomes dangerously high, the roadways are cleaned to a depth of 4 or 5 in. and a new application is made.

In dusting main return aircourses all loose coal and rock is loaded out, the ribs and roof being washed down several times. Every 500 or 600 ft. the stoppings between the main and return entries are broken through, and small doors are installed. Blowers are used to force the fine dust into the return aircourses through these openings. Thus suspended the dust travels a long distance before it is deposited on the floor, ribs, and roof. The material used is chiefly adobe, sun-dried and screened on the outside of the mine. A two-ton car load of this dust will cover several hundred feet of airway as little loss occurs, the deposit being from 2 to 6 lb. per running foot of entry.

Blowers are used to force the dust into the main returns. One unit consists of a small blower mounted on a truck with a 2-hp. motor. A 6-in. pipe is attached to the blower and runs the full length of the truck with a projection over the end. A hopper is built over the pipe and connected. Stove pipe or canvas tubing is led from the pipe through the door in the stopping so that the dust is discharged into the return air current.

But adobe is not commonly used in the Colorado, Utah and Wyoming mines which are now industriously dusting. There, the tendency this fall is to swing from surface dust to finely pulverized limestone. A number of pulverizing plants are now installed and more are in prospect.

The consensus is that dust coarser than 200-mesh is practically worthless and that a large proportion of it should be of 300-mesh. The 1924 report of the Rocky Mountain Coal Mining Institute's safety committee specified that rock dust "should be 100-mesh or finer." Since it was written, the western mining fraternity has come to put more and more emphasis on the "finer."

Though trough barriers have been installed in several Rocky Mountain mines, usually in batteries of six or more at all panel entries and at the bottoms of

slopes where the supposition is that they will be dumped by runaway trips, the main dependence is placed upon preventing explosions rather than upon stopping them. For more than a year intensive effort has been made to develop portable dust blowers of one type or another, each equipped with a fan distributing dust that is fed into the air stream from some sort of a hopper.

The tendency this fall, however, is to desert low-pressure dusting for that done by higher pressures. Such companies as the United States Fuel Co. and the Utah Fuel Co., both in Utah, and the Phelps Dodge Corporation in New Mexico, are introducing air-compressor units to provide air for blowers. With high-pressure air, a smaller quantity of dust will serve—usually less than 3 lb. per lineal foot of entry—and the fine coal dust on roof and ribs is more effectually dislodged. William Littlejohn, general superintendent of the Utah Fuel Co., feels that in the Castlegate and Sunnyside, Utah, mines of his company, the waste of pulverized limestone is reduced to a minimum by this process. Labor costs of dusting also are reduced.

Wet "dusting," which was developed in the Rockies,

High-Pressure Rock Dusting at Hiawatha

Machine being operated by the United States Fuel Co., of Utah. This machine was devised because of the belief that low-pressure application of rock dust is more expensive and less efficacious than application under high pressure. The force of the stream is sufficient to make much rock dust stick to the dusted surfaces.

is making progress too, thus combining in one process the westerners' double confidence in water and inert dust. "Muditing," which started in the Phelps Dodge mines by the use of a cement-projecting machine and which was advanced at Wattis, Utah, by W. J. Reid, superintendent for the Lion Coal Co., who greatly cheapened the process with a new sprayer of his own invention, is getting wider attention.

The Reid mud sprayer, which succeeds in filling every crack and crevice in roof, ribs and floor, and which washes down coal dust to the floor and agglomerates fine coal with the mud, has been viewed by most of the coal-mining people of the West. The general conclusion thus far drawn by them is that the scheme is a decided success for dry mines and that an occasional coating of mud is good for any mine as it seals up dust-catching holes and cracks and rounds off projections where coal dust might settle.

Mr. Reid set out last September to prove the efficacy of mud by experiments in a 50-ft. length of corrugated iron pipe. This did not prove practicable. Today exhaustive experiments are progressing in an entry 5 ft. wide, 7 ft. high and 250 ft. long that has been driven from the outcrop into a seam of coal about 50 ft.

**Another View of the Hiawatha Rock-Dusting Trip**

A portable compressor is mounted on a mine-car truck, an injecting device is installed as in the use of a sand blast, and two cars of fine dust are taken along. The outfit then is drawn through the mine against the air, and three men—motorman, nozzleman and assistant—do the mine dusting with reasonably high speed.

below the seams in which the Lion Coal Co. is working at Wattis.

## Engineers Hear How Coal Firm Entered Power Business

Electrical Engineers of Lehigh Section Hold Big Session and Discuss Power and Load-Factor Betterment

**H**OW a coal company formed the largest public-utility electric plant in the northeastern part of Pennsylvania and one that uses more anthracite than any other plant in the world, was the dramatic story of G. M. Kennedy, electrical engineer, Lehigh Coal & Navigation Co., at a meeting of the Lehigh Valley Section of the American Institute of Electrical Engineers held Nov. 21 in the Schuylkill County Country Club, near Pottsville, Pa.

Never in the history of the anthracite region has such a large and representative group of electrical engineers gathered together. Nearly 300 were present, some being coal-company officials and others representatives of public-utilities.

The main feature of the evening was the address by G. M. Kennedy. He told the early pioneering history of an electric light and power company which, fostered by his corporation, has now a leading part among such institutions. Early in 1905 the Lehigh Coal & Navigation Co. installed a plant to operate lights and a few mining machines and to supply energy to towns near Lansford for light and electric-railway systems. By 1910 the plant was inadequate, so large had become the demands for power. Consequently plans were laid for the Hauto plant.

Though the Pennsylvania Power & Light Co., the present owners of the plant, have a general load, about 60 per cent of the total demand is for mining. The load curve of the power company is so largely influenced by the demands of the coal companies it serves that it shows all the characteristics of the load curve of an anthracite mining plant. Between 10 and 11 o'clock in the morning the load is heaviest. During the night the load is nearly uniform, due mainly to the pumps, slight variations being introduced by the use of the power for street and residence lighting in the various towns served by the company.

Much about electric transmission and power use was

The intention is to sprinkle roof, walls and floor with water and place 1 lb. of coal dust per lineal foot throughout the whole length to determine the explosibility of Wattis coal dust. Then the entry will be reloaded with coal dust and given one coating of mud. If this explodes, two coatings of mud will be applied and the test run again. Mr. Reid does not believe the first coating will permit an explosion but if it fails to do its job, and if two coats fail, then he will install rock-dust barriers along with mud applications, and so on until he knows positively what protection his mud-spraying method will give.

Some scheme of spraying mud may soon be adopted by many mountain mines on main entries in order to give such passages a non-combustible coating similar to that provided by cement but much cheaper. This, with the lavish use of water at and near working faces, and with dry dust blown through side entries and rooms at high pressure, is the combination of protective systems which the West is adopting swiftly and which has developed out of the long years of study the West has given the subject.

learned during the pioneer work of the coal company. When old equipment had to be replaced, electricity was given an opportunity, and it soon proved that it had many advantages. Even the manufacturers learned much while this process was in operation. The electric loads soon became so large that the rupturing capacity of switches came to have a real meaning. When switches failed under less than their rated rupturing capacity, manufacturers were compelled to make further researches and better their designs.

"Power-factor correction has become a real problem," said Mr. Kennedy, "but it is a regrettable fact that the power companies have attacked it in an unsatisfactory manner. The penalty clause in the power schedule should be eliminated. When a power company approaches a customer with a penalty clause in its contract, it appears to be carrying a chip on its shoulder. The power purchaser feels it is seeking trouble."

But because power-factor correction is a vital matter we must not overlook the importance of the regulation of the load. Also, much can be done by coal companies to better their load factors. At one mine of the Lehigh Coal & Navigation Co. by careful adjustment the load factor was increased from 34 to 51 per cent.

Conditions at no two mines are alike but the accompanying figures showing the quantities of energy used for the various operations at some of the Lehigh Coal & Navigation Co.'s mines are interesting.

### Energy Requirements, Lehigh Coal & Navigation Co.

Use	Kw.-hr. per Ton
Locomotive haulage .....	1.5 to 3.3
Ventilation .....	1.5 to 4.5
Pumping .....	2.0 to 8.5
Hoisting .....	1.0 to 1.5
Breaker .....	3.2 to 6.0

The new Coal-dale breaker of the Lehigh Coal & Navigation Co. requires about 241,000 kw.-hr. per month. Usually about 10,000 kw.-hr. of electrical energy are required per month for lighting.

Other speakers at the meeting were M. G. Reinicker, superintendent of operation of the Pennsylvania Power & Light Co. and C. M. Gassaway of the East Penn Electric Co. Both of these men spoke of their work in its relation to the generation and distribution of energy to coal-mining companies. W. H. Lesser, electrical and mechanical engineer, presided at the meeting.

*Stripping Electrically*

## Stripping a Twice-Worked Anthracite Basin

Modern Machinery Makes Total Recovery Possible—Surface Removed from Old Mine Workings—Giant Electric Shovel Used—Ward-Leonard Control Employed—Automatic Dump Cars Make Quick Work of Spoil Disposal

BY FRANK H. KNEELAND  
Associate Editor, *Coal Age*, New York, N. Y.

**I**N MANY localities throughout the anthracite region may be found coal properties that were considered as being worked out long ago and were accordingly abandoned. With the lapse of years not only have improved methods and means of working being enhanced but the value of the product has been greatly enhanced. As a result, many properties that were formerly worked by underground methods are now being reopened by stripping.

Such an operation is that the Cranberry Creek Coal Co. in the Crystal Ridge basin of the Mammoth coal bed, near Hazleton, Pa. This stripping eventually will be 2,700 ft. long and about 500 ft. wide. The maximum depth to the top of the coal or the greatest thickness of cover to be removed will be approximately 165 ft., and the minimum thickness of cover will be 95 ft. The total volume of overburden to be removed will aggregate about 4,000,000 cu.yd. Approximately 90 per cent of this spoil will consist of hard sandstone and fine conglomerate and the rest will be made up of surface soil, clay and drift. It is estimated that it will require five years to remove the overburden and extract the coal.

Prior to 1911 both outcrops of this basin were stripped to a depth of approximately 40 ft. The bed now being uncovered is about 25 ft. thick, and pitches at a maximum inclination of about 45 deg. It received

"Do it electrically" is a slogan that has recently been applied to coal stripping as may be seen in the headpiece. The giant shovel is shown making the first cut in the Crystal Ridge stripping near Hazleton, Pa. It will require about five years and the removal of approximately four million cubic yards of overburden to complete the job.

its "first mining" long ago. Much coal, however, yet remains in the old pillars as well as in the tops of the old rooms or breasts.

In order to strip this coal efficiently new equipment of modern type has been purchased. This consists of a huge electric shovel, three 40-ton saddle-tank steam locomotives, seven 30-cu.yd. automatic air-dump steel cars and five 6-in. electric well drills. These latter machines are employed in putting down shotholes by means of which the cover is blasted loose so that the shovel may handle it. Even after this preparatory blasting, however, the stripper has to do the hardest kind of digging.

### ELECTRIC STRIPPER IS A VERITABLE GIANT

Interest in this stripping centers in the big Bucyrus, full-revolving, electric shovel employed. This is one of the largest machines of its kind yet built and the first electric coal stripper to be employed in the anthracite region. Some of the more important dimensions of this shovel are as follows: Capacity of dipper (struck measure), 6 cu.yd., (heaped measure), 7½ cu.yd.; length of boom (lower end to center of hoisting sheave), 85 ft.; length of dipper handle, 58 ft.; maximum height of dump above rail (boom at 45 deg.) 65 ft.; approximate working weight, 760,000 lb.; dumping radius at maximum dumping height, 94½ ft.; maximum dumping radius (dumping height 48 ft.), 97½ ft.; radius of cut (at 40-deg. elevation of lip), 101½ ft.; radius of cut at bottom of pit, 59 ft.; radius of rear end of revolving frame from pivotal center,

33 ft. 4 in.; overall width and length of revolving frame, 20 ft. 1 in. x 49 ft. 8 in.; height of A-frame above top of rail, 50 ft. 2½ in.; size of lower frame (center to center of main girders), 30x30 ft.; diameter of roller circle, 30 ft.; number of rollers, 84; diameter of rollers, 10½ in.; pitch diameter of rack gear on lower frame, approximately 26 ft. 9 in.

The base of this machine, which, as has been stated is 30x30 ft. in plan, is mounted on four propelling trucks, or one at each corner. These are of the four-wheel equalizing type, all the wheels being double-flanged drivers. Three-point suspension is provided, two trucks being attached to the base directly and the other two supporting an equalizing beam that is attached to the base at its center. An even distribution of load on the trucks is thus obtained.

Jackscrews are attached to either end of the equalizing beam immediately above the truck centers. When the shovel is in operation these screws are tightened between the truck and a plate on the shovel base, thus relieving the equalizing beam of excessive load. When the shovel is to be moved these screws are slacked off leaving the trucks free to follow any irregularities of the track.

Power for propulsion is transmitted through a vertical shaft extending downward through the pivotal center of the machine and geared to the shaft of the hoist drum. A jaw clutch engages or disengages the propelling mechanism. The vertical shaft drives a horizontal transverse shaft beneath the base, which at its extremities carries double chain sprockets provided with jaw clutches. This arrangement permits the driving of all trucks or those of one side only. Chains connect these sprockets with the intermediate shafts of the trucks. These chains are of the pin-and-bar type and have a positive grip on the sprockets.

#### TRANSMISSION MADE BY ALTERNATING CURRENT

Three-phase alternating current is brought to this machine at 2,200 volts by means of suitably insulated cables passing over the side of the bank and thence down into the open cut. At the center of rotation of the upper frame of the shovel suitable collector rings are installed. These are provided with brushes and serve to conduct the current from the stationary base to the revolving superstructure. These rings are adequate for the purpose intended and readily accessible for inspection.

Upon entering the machine current is passed through a Ward-Leonard controlled motor-generator set which furnishes direct current to the hoist, swing and thrust motors. This machine is a direct-connected five-unit set mounted in the rear end of the revolving frame. It is so designed that it will operate successfully, even when the shovel is working on a considerable grade. This set is driven by a 435-kva. 0.8-power factor synchronous motor, directly connected to and mounted upon the same bedplate with the hoist generator which is rated at 150 kw. and 250 volts direct current. This latter machine is fitted with differential compound windings. The exciter, which is also direct-connected, is rated at 20 kw. and 125 volts. This machine is flat compound-wound. The swing and thrust generators rated at 75 and 50 kw. 250 volts direct current respectively, both differential compound-wound, are mounted on a separate bed plate but are driven through a flexible coupling.

Three 7½-kva. single-phase transformers supply low-voltage alternating current to a small air-compressor

Fig. 1—Six Cubic Yards at One Dip of the Bucket

An idea of the kind of material that the shovel must handle may be gained from the rocks in the foreground. Despite the sturdy construction of the dipper the renewable points of the teeth are occasionally torn off by the severe digging.

motor, to the dipper-trip motor and to the lights carried on the revolving frame.

The main hoist is driven by two motors each of 225 hp. The main hoist cable is single, of 2½-in. diameter and is wound on a grooved drum, machined to a pitch diameter of 54 in. This drum is of sufficient length to permit the hoist rope to be wound to the highest position of the dipper without exceeding a single layer. The drum carries two outside friction bands lined with basswood blocks. These frictions are operated by an air cylinder.

The mechanism operating the lowering brake is controlled automatically by means of a spring, an air cylinder and a magnet valve. This, however, does not prevent the brake from being applied by means of a foot treadle.

The swinging motor drives a vertical shaft through two spur- and one bevel-gear reductions. A spur pinion on this shaft engages the swing rack on the base of the machine and a friction clutch protects the mechanism from overload. The second intermediate shaft of this mechanism carries a band brake that is applied by means of a strong spring and is released by an air cylinder.

On this shovel the boom is built up of structural steel shapes and plates and is of the box-girder type. It consists of heavy angles at the corners connected on all four sides by plates. Diaphragms are placed at suitable points along its length to afford torsional strength. At its lower end heavy steel-casting feet, securely riveted to the plates and angles, are provided. Wire guy ropes extend from a point near the center of the boom to the outer sills of the revolving frame. The boom is provided also with independent safety guys.

The thrust motor, and the intermediate and shipper

shafts are mounted on two steel foundation plates securely riveted to the boom. Two saddle blocks are mounted on the shipper shaft, each straddling a rack pinion and one member of the double dipper handle. These saddle blocks are of heavy design and of the roller type. All this machinery is protected from overload in case of emergency by a slipping clutch. The intermediate shaft is provided with a band brake which is applied by means of a heavy spring and released by an air cylinder.

It has already been stated that the hoist rope is single, and of 2½-in. diameter. The sheave at the point of the boom over which this cable passes is of 90-in. diameter; the groove in its rim is machine-cut and the hub is bronze-bushed.

The boom is suspended by a 12-part tackle and is raised or lowered by means of a drum geared to the main hoisting shaft. This drum is carried on an independent shaft, is actuated by a jaw clutch, and is held by a dog which engages a ratchet wheel when the shovel is in operation.

#### DIPPER AND HANDLE MADE "EXTRA STRONG"

As in many of the large shovels of recent construction the dipper handle on this machine is double. That is, it is composed of two members straddling the boom. These two members are tied securely together at both ends by means of heavy separators, built up of plates and structural shapes. Each member of this handle consists of a wooden beam reinforced with steel bars. The racks fastened to their under sides as well as the pinions meshing with them are nickel-chrome steel castings. The dipper is attached to the extremity of the handle by means of steel hinge castings.

The dipper is of the square-back type, fitted with four center or digging teeth, provided with renewable points. The digging that this shovel has to perform is of the hardest kind, and the dipper is built to withstand the extreme duty and wear to which it will be subjected. Spring buffers are provided on the door hinges to absorb the shocks entailed in dumping.

A somewhat unusual but highly efficient detail embodied in this machine is the equipment used for tripping the door of the dipper. This operation is performed by means of a small totally inclosed alternating-current motor mounted on the under side of the dipper handle. The shaft of this motor is coupled to a drum upon which the trip rope, or in this case a

chain, is wound. To discharge the contents of the dipper, therefore, the shovelman merely closes a switch. This energizes the motor, which in turn trips the dipper.

All the direct-current motors installed on this machine are of General Electric make, designed to withstand the high peak loads, and the intermittent, varying-speed, reversing service incident to shovel operation. They are of steel-mill type with steel-casting frames, split horizontally, and fitted with fire-proof insulation, commutating poles, and series field windings. The frames are of the open type on the hoist and swing motors but of the inclosed type on the thrust motor.

All these motors are controlled by varying the fields of the generators that supply them with current, a separate generator being provided for the hoisting, thrusting and swinging operations. Master controllers manipulated by the shovel runner govern the generator field current, thus varying the speed, torque and direction of rotation of the several motors. The maximum torque of the hoist and thrust motors when the dipper is stalled in the bank, or that of the swing motor when it is accelerating, is limited by the differential field winding of the generators. As the current taken by the motor increases, the series field of the generator builds up, counteracting the shunt field, thus limiting the current taken by the motor. This holds the motor torque to a safe value even when the shovel operator holds the controller handle full on.

The hoist controller is so arranged that the weight of the descending dipper and handle drives the hoist motor as a generator, thus returning energy to the power line. This arrangement not only saves power and practically eliminates brake wear, but also makes the shovel easy to operate as it obviates the necessity of disengaging the hoist friction, lowering the dipper on the foot brake and then throwing the friction in again when digging is to begin.

All motors are protected against plugging or reversing, so that the machine cannot be jerked or the commutators damaged should the operator reverse the motors while they are running. All brakes are controlled by the motor controller handles through magnet valves. Thus any brake is set when its controller handle is in the off-position. The brake is released when the handle is thrown to either forward or reverse running position.

FIG. 2

#### Loading a Trip

Spoil may be placed on the car 187 ft. horizontally from, and 65 ft. above, the point from which it is dug. As shown, the dump cars may thus be spotted well back on the wide berm, provided alongside the shovel. This is an excellent feature where the ground is loose and the track accordingly uncertain.

An emergency trip is provided. Thus the shovel runner can apply all brakes and "kill" all generator fields almost instantly by pushing a conveniently located button. An alternating-current motor-driven compressor of about 25-cu.ft. per minute capacity, fitted with reservoir and governor, furnishes air for the operation of the various clutches and brakes. The pressure carried is about 90 lb. per square inch.

The lighting equipment comprises two flood lights, so mounted as to illuminate the operations of the dipper, and a number of smaller lamps lighting the interior of the shovel house, the various machinery units, the outside platforms and the area immediately surrounding the machine. A portable lamp with extension cord is also provided. All light wiring is in conduit, and 110-volt bulbs are used. So far as possible all electrical conductors are run in conduit.

Spoil dug from the bank is discharged into Clark automatic air-dump cars, each of 30-cu.yd. capacity. Each of the 40-ton locomotives can handle two of these cars per trip. It normally requires from five to seven dips of the shovel to fill a car. These cars and locomotives operate over standard gage (4 ft. 8½ in.) tracks laid with 80-lb. rails. The maximum distance the spoil is hauled will not exceed two miles and the steepest gradient traversed will not exceed 2½ per cent.

Arrived at the spoil bank both cars of a trip are dumped almost simultaneously by one man who merely throws a small lever or cock upon each car. Fig. 3 shows two cars in the act of dumping. Compared with the small hand-discharged contractors' side-dump car, used even today at many stripping operations, these cars represent a big step forward.

This Crystal Ridge stripping offers a good example of how coal deposits, or what is left of them, are today being reclaimed through the use of modern equipment. This basin of coal was first "worked out" by underground methods and abandoned. Next the outcrops were worked by steam shovel and after these machines had gone as far as their economic limits would permit the deposit was again abandoned. Now comes the big electric shovel by means of which all the coal left by the earlier methods—which forms a goodly portion of

Fig. 4—Shovel Is Excavating a Natural Basin

Like most of the coal beds in the anthracite region, that at Crystal Ridge is folded. The crop has already been stripped and the rest of the coal has been partly worked, but much of it still remains and it is profitable to remove as much as 165 ft. of cover to get at it, as the bed is 25 ft. thick, and the product will be that luxury coal, anthracite.

the original deposit—will be reclaimed. This is true conservation. The same means and methods that are used here doubtless can be applied to many other coal basins throughout the anthracite region and elsewhere.

### Experiments on Rope Testing Progress

Investigations are being actively prosecuted into the fatigue of ropes by the U. S. Bureau of Standards, says the annual report of the Director. An advisory committee composed of representatives of national technical societies, Government departments, and large users and manufacturers of wire rope was organized and has been of great assistance in outlining the investigation.

The method which appeared to be most promising is that of magnetic analysis. This method has received much study as a nondestructive means of testing iron and steel products, but it was at once recognized that no magnetic means has yet been developed which gives results that are unambiguous and capable of definite interpretation. Therefore it was necessary to make investigations of a basic and fundamental nature to establish the relations between the magnetic properties of wires used in wire rope and the effect of the various causes of deterioration in wire rope in service.

A study of the effect of mechanical stress on the magnetic properties of steel wire has been completed and is nearly ready for publication. An investigation of the effect of wear is nearly completed, and work is in progress on the effects of fatigue and corrosion. Apparatus for field tests of rope is being designed and constructed.

FIG. 3

#### Over She Goes!

Two 30-cu.yd. car loads of spoil are being dumped simultaneously by one man who merely throws two small levers. This operation is in marked contrast to the discharge of a trip of small hand-operated dump cars such as are still in use at some strip-pings. The height of the car above the rail makes the rock fall some distance from the track making it possible to keep the ties well back on the solid.

# One Company Meters Its Loads at a Common Point Cutting Electric Bills 19 per Cent

Distribution Lines Have Their Peak Loads at Different Times, Hence, When Energy Is Measured at a Central Point the Combined Demand for Power Is Relatively Steady, Earning the Company a Better Rate

BY A. MACDONALD

Chief Engineer, Keystone Coal & Coke Co.,  
Greensburg, Pa.

**T**ODAY, MOST COAL operators admit the economy of purchased power, but many let it go at that, apparently not realizing the possibilities of what can be done at their end of the line toward cutting their power costs. The Keystone Coal & Coke Co., of Greensburg, Pa., has made surprising reductions in cost by giving close attention to the utilization of electric power and by a unification of distribution lines so as to be able to take advantage of a central metering point.

Definite figures cannot be given of the savings which the various changes hitherto made have effected because the present methods of keeping records have grown up rather than been inaugurated at a definite date. However, on the new distribution system concrete figures are available, and the officials are quite certain that an average saving of 19 per cent in monthly power bills has been made. In a field where power costs can be expected to run as high as 18c. per ton this saving is no insignificant sum.

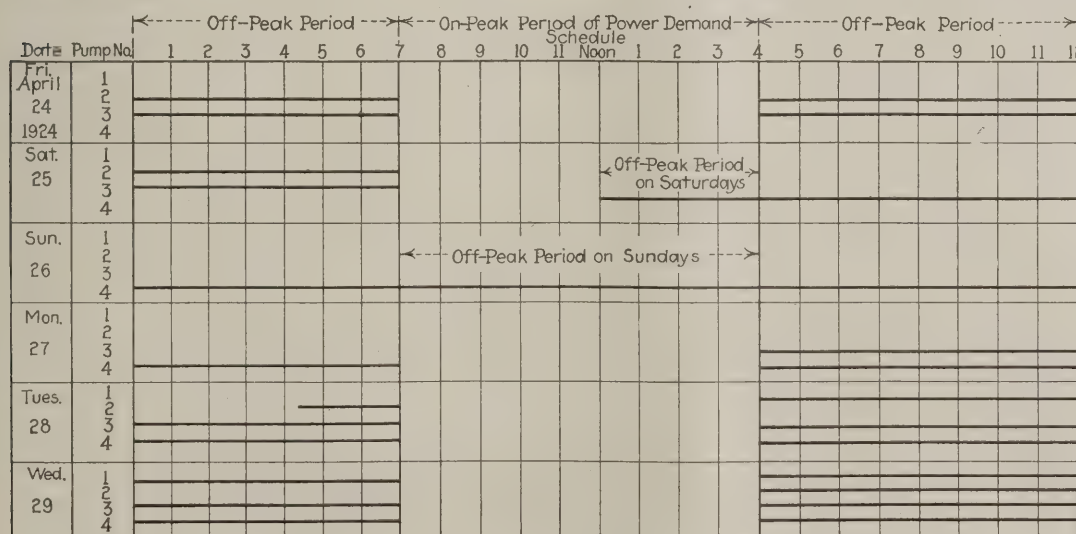

It was made possible by an arrangement, which the coal company completed last April, which provides for a central metering point at which is measured all the power purchased for the operation of its mines in the Greensburg basin. Formerly the monthly bills were computed from readings of six metering stations connected to 2,300-volt lines. Now all power is purchased at 25,000 volts and is metered at one central point. To make this change a large investment was made to install a new 25,000-volt distribution line and new switching, metering and transformer equipment. However, the rate of return on this investment is such as to make the installation stand out as an example of what can be done by taking advantage of wholesale power rates.

When considering the changes necessary for establishing a central metering point a careful estimate of the possible saving was made. After an exhaustive study of the demand charts of the six existing metering stations had been made it was estimated that the new arrangement would make possible a reduction of 17 per cent in the total power cost. The fact that this figure is so close to the saving of 19 per cent actually made indicates the accuracy with which such results can be predicted when dependable information such as that supplied by meter charts is available.

Power for this group of mines in the Greensburg field, and also for the other operations of the Keystone Coal and Coke Co., is purchased from the West Penn Power Co. The bills are computed according to Schedule J which is about the last word in rate making as based on the many and varying conditions affecting the cost of power delivered to the customer.

This schedule, allows a premium to customers who co-operate with the power company by helping it to reduce line losses and the equipment investment necessary for the delivery of power in such quantity and at such times as is desired. The company can do this by improving the power factor, reducing the instantaneous and 15-min. demands, controlling the load so as to hold down the demand during certain periods of the day and by concentrating loads and thus co-operating with the public utility company.

The new 25,000-volt central metering station is equipped for a capacity of 6,000 kw. To date the highest peak load has been 2,500 kw. However, at present, with the mines operating at approximately 55 per cent capacity, 195,000 tons per month, the 15-min. demand is only about 1,800 kw. The new metering station is located at Crows Nest mine, which is near the center of

## Visualizes Load

The heavy lines represent the periods of the day when each pump is in operation. This graph was made from the information reported from the Hannastown mine. When the graph is made it quickly shows the length of time each pump was in service. It is easy to detect which, if any, pumps are running during the on-peak period of the day. Note that on Saturday afternoon and all day on Sunday the pumps may be operated without being considered on-peak load.

the Greensburg basin and therefore at the most advantageous point for the six operations served.

A noteworthy feature of the installation is the fact that the coal company also has its own set of meters, these being connected at the same point in the 25,000-volt line as those of the power company. There are two reasons why the coal company should have its own meters. Not only does it have the satisfaction of having a check on those of the power company, but by this provision it is enabled to have desirable charts and records for study.

The two sets of meters are mounted in weatherproof cast-metal boxes, installed out of doors on a concrete

former substation. These meters provide a means of determining just what saving is being made by the new arrangement. The combined demand at the common point, which is the billed demand, averages about 25 per cent less than the added demands of the six distribution meters. This reduction is due to the diversity factor, in other words to the fact that the 15-min. peaks of the various mines do not occur at exactly the same time. This 25-per cent decrease in demand is the item which cuts the largest slice off the company's monthly power bill.

The Keystone Coal and Coke Co. has now been operating since last April on the new arrangement and has

#### Where Savings Are Made

The steel tower, arresters and instrument transformers are part of the new 25,000-volt central metering station which has made it possible for the Keystone Coal & Coke Co. to save 19 per cent on its monthly power bills. The transformers and wood pole structure at the left are part of the 25,000-volt to 2,300-volt Crows Nest mine substation.

platform. This platform is at the base of the steel structure which supports the disconnecting switches and choke coils, and on which the instrument transformer connections are made to the 25,000-volt line. The boxes are set on concrete pedestals so that the meters are at a convenient height above the ground. The curve-drawing wattmeter is the most useful instrument that the company owns. It is from the charts of this meter that the average demand for the highest 15-min. load period of the month is obtained. Ordinarily, the maximum-demand records of the coal company and the power company are surprisingly alike. However, differences do occur, and when this happens representatives of the two companies get together and by comparing their charts easily locate the error and adjust the difference.

To distribute the power from the new central metering point at Crows Nest the coal company had to build about 18 miles of 25,000-volt lines. Wood poles and pin insulators are used, and disconnecting switches are installed on each branch. The line is well protected by oxide-film lightning arresters, one set being located at the metering point and one at each of the six transformer stations.

A curve-drawing wattmeter, owned by the coal company, is installed in the 2,300-volt line of each trans-

found that the saving in power will pay for the entire installation in from three to five years, depending, of course, on the mine production.

Fully realizing the desirability of keeping down the maximum demand the company makes every effort to dispatch the loads to the best advantage. About the only really flexible part of the load is that established by the large centrifugal mine pumps. The pumpmen are instructed to see that the sumps are free of water and the pumps stopped before 7 a.m., which is the beginning of the on-peak period of the power schedule.

Except for possibly two or three months of the year, no pumping is done in the day time. In wet seasons, when it becomes necessary to pump during the day, as much as possible is done at periods which do not coincide with the peak loads caused by the operation of cutting machines, mine locomotives, hoists, fans, tipples and washeries.

To be able to check and dispatch the loads it is necessary to have charts indicating the load characteristics of each important machine. Here is where the charts from the demand meters play another important part. The six distribution meters are geared for a chart speed of 3 in. per hour. The main meter is geared to 4 in. per hour. These charts properly show the characteristics of the load on each line.

Pumping Reports Like this Are Made at Every Mine. From These Records the Engineering Department Plots a Service Graph

Every mine submits a report showing the time each pump is in operation. All pump men are instructed not to run or even start a pump during the on-peak period of the power schedule. Aside from advantages to the power company there are many advantages to the coal company if it takes on-peak power only for that equipment which must be operated during that period. A pumping load added to the day load of the mines increases the maximum demand charge even if a pump runs for but a short interval of time.

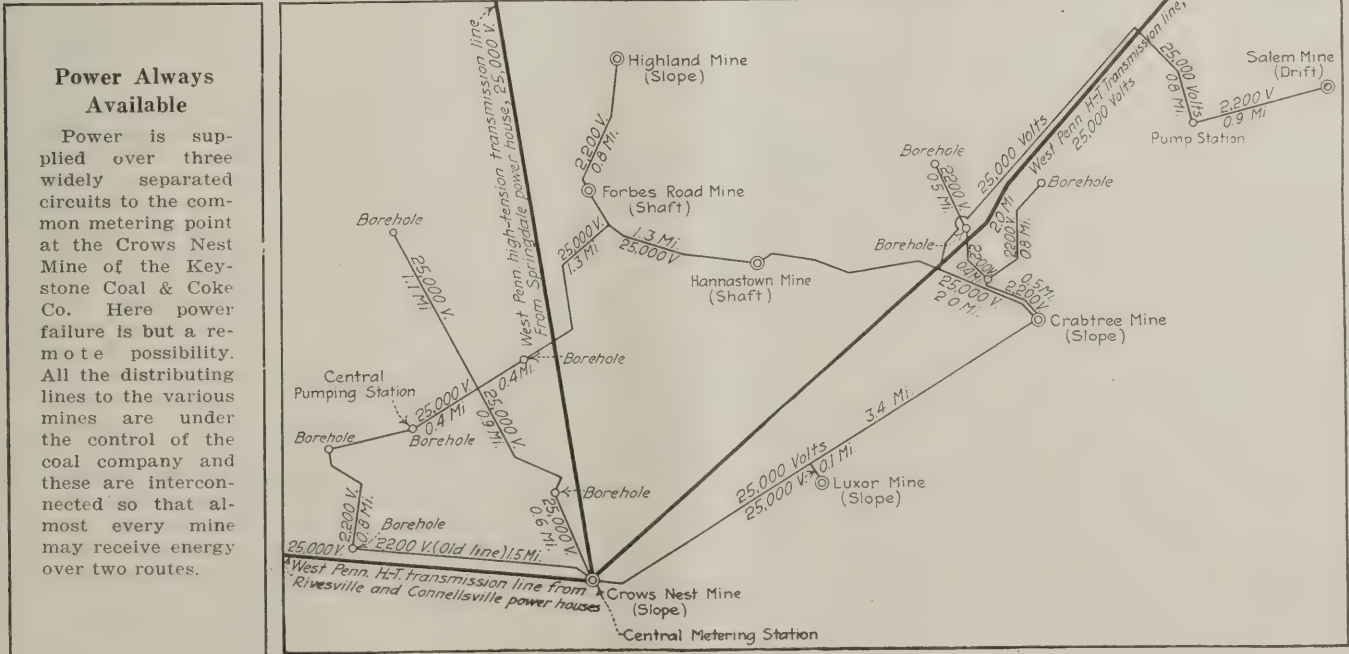

The charts from these meters are used with the daily pump reports for determining if the pumps are responsible for any of the peak loads. The pumping records show the total hours and the exact time of day or night that each pump was in operation. A graph is made of these data, the operating periods of the various pumps being indicated by a series of colored horizontal lines. It requires but a glance at this graph to determine if any and how many pumps were operating at a given time.

In case it is found that a pump was running at the time of a peak load an investigation is made to determine if the pumping was necessary. As the larger pumps are equipped with 400-hp. motors, the operation of any pump shows up clearly on the chart of the respective distribution meter, even though it takes place at the same time as the heavy fluctuating day load. This

fact makes it possible to check at any time the daily reports made by the pumpmen and therefore prompts the men to keep accurate records.

The methods taken by the Keystone Coal and Coke Co. to obtain the most advantageous power rate, and its constant effort to hold down the maximum demand has resulted in reducing its overall cost per kilowatt-hour so as to compare favorably with that of the customers of the West Penn Power Co. having the lowest rates. Low rates, of course, are not the only consideration of purchased power.

The Keystone people report that interruptions are almost unknown. Although the company operates mostly shaft mines, and electricity is used to the exclusion of steam for all drives, such as ventilating fans, hoists, pumps and driving generating units, no auxiliary drives have been found necessary.

Marvel Village, Bibb County, Alabama

## Marvel Plant Largest of Any in Cahaba Field

All Coal Drawn from Steep Slopes—Pitch Near Surface 15 deg.—Vibrating Screens and Tables Used for Cleaning Coal  
—Equipment Provided for Every Ordinary Type of Repair

ONE OF THE leading mines in the Cahaba field of Alabama is that of Marvel, belonging to the Roden Coal Co. The coal which is of the Clark seam is 48 in. thick and lies at the outcrop on a pitch of 15 deg. At a point 5,000 ft. distant from the outcropping the pitch has decreased till it is only 5 deg. It is estimated that the bottom of the basin will be reached 3,000 to 4,000 ft. further in. The coal is a high-volatile bituminous fuel and makes an excellent domestic fuel, of the following analysis: Moisture, 0.57 per cent; volatile, 36.81; fixed carbon, 57.96; ash, 4.66; sulphur, 0.65. Its heating value is 14,200 B.t.u. As the coal has a rash under it and a parting, that at times disappears and at other times is 3 in. thick the screenings have to be washed.

The coal is loaded at the face in  $1\frac{1}{2}$ -ton mine cars. It is hauled by mules to the slope, assembled into fifteen-car trips and hoisted to the tippie. At Mines Nos. 2 and 3 the slopes have double tracks. Coal from No. 3 mine is hauled by a 16-ton steam locomotive over a track laid with 60-lb. rail to the tippie of No. 2 mine.

Here, coal is discharged on a crossover dump into a 20-ton bin from which it is delivered to a plate feeder which in turn delivers it to the main shaking screen, where three sizes are made; 3-in. screenings, 3x6-in. egg and 6-in. fancy lump. The lump and egg sizes then pass over loading booms to railroad cars, the screenings being conveyed to a 1,500-ton coal bin. Under this bin run two concrete tunnels where, on apron conveyors, coal is conveyed to four universal vibrating screens on which the coal under  $\frac{1}{4}$ -in. is removed for washing on two Plat-O and two Deister-Overstrom tables.

The coal between  $\frac{1}{4}$  and 3 in. is washed on two Shannon jigs. After the coal leaves the jigs the  $\frac{1}{4}$ - to 3-in. coal may be remixed with the coal under  $\frac{1}{4}$  in. and loaded as 3-in. steam or it may be passed over a shaking screen, where the 1x3-in. nut is taken out. The  $\frac{1}{4}$ - to

1-in. coal is then mixed with the coal below  $\frac{1}{4}$  in. to make a 1-in. slack. Nut coal, when made, is conveyed by a belt conveyor to a 90-ton bin over the railroad track and rescreened before loading into cars. It is then carried by loading booms and discharged carefully by them into the railroad cars. The ash in the 1-in. washed slack and in the 3-in. steam averages from  $6\frac{1}{2}$  to 8 per cent.

One-inch slack is used in the Wickes vertical water-tube boilers for the generation of steam at the mine. Of these there are three, each of 300 hp. capacity and equipped with Murphy stokers. Natural draft is provided by a steel stack, 150 ft. high and self supporting. Its diameter at the base is 14 ft. and at the top, 6 ft.

At No. 2 mine the coal is hoisted up the slope by a 28x48-in. double engine with an 8-ft. drum having steam-operated brakes, friction and reverse. The hoist at No. 3 mine is a 24x36-in. double engine with a 6-ft. drum having steam friction but brakes which are operated by hand. Two belted Sirocco fans are installed, one of 72-in. and the other of 96-in. diameter. These are belted to 2,200-volt induction motors. To remove the water collecting in the mine three four-stage centrifugal pumps are provided capable of acting against a 436-ft. head, one with a capacity of 280, one of 440 and a third of 570 gal. per minute. Single-drum electric hoists are used for sinking slopes and manways and small triplex pumps, motor-driven, remove the water from the slope faces.

Mine No. 3 has four inclined entries, the two center slopes measuring 7x10 ft. and being used for haulage. The return airways which are placed one on each side of the haulageways measure 6x13 ft.

Permanent construction has been used everywhere. The boiler house, power house, shop and fan house are of brick with steel roof trusses and a tile roof. The washer, tippie and No. 3 hoist house are of steel-frame

construction covered with galvanized corrugated iron. Steel window sash affords copious light. The equipment in the power house outside of the main hoist for No. 1 mine is a 150-kw. and a 225-kw. steam driven 2,200-volt generator with a five-panel switchboard and a 10-ton crane which travels the full length of the building.

The shop contains a 50-ton hydraulic press, a 6x6 power hack saw, a 22-in. x 8-ft. engine lathe, a bolt and pipe machine, a power punch and shear, a 26-in. drill press, a 6-in. pipe machine, a power hammer, an air compressor, a rock-drill sharpener, a band saw, two blacksmith's forges, four emery wheels, a welding and cutting outfit and electric and air drills for wood and metal—quite a complete equipment for a plant only thirty-one miles from a big and well-equipped city like Birmingham. Scrap lengths of round iron are bolt-headed on the drill sharpener by the use of special dies and then threaded on the bolt machine.

Two supply houses keep the mine free from delays. One house, measuring 28x78 ft. keeps small items in

Company Store at Marvel

This store, which supplies almost every conceivable need to the over three hundred families domiciled in Marvel, measures 60 x 120 ft.

stock, the other, which is two stories high and 48x60 ft. in plan, is used to keep on hand heavy items such as reserve pumps, wire ropes, sheaves, pipe, bar iron, large gears, dwelling-house repairs, such as doors,

#### The Seams in Alabama Lie in Basins the Outlying Edges Often Dipping Heavily

The largest coal field is the Warrior of which the Plateau field forms a part. The latter field, however, has not in general been found profitable to operate. The Coosa field also is little operated. The Cahaba field, in which is the Marvel Mines of Bibb County, has several active mines, engaged in the production of coal for domestic and industrial purposes. It is 68 miles long and 5 to 8 miles wide and it covers a surface area of 39½ square miles. Most of the seams pitch, have a weaker roof than those in the Warrior field and make more water than the seams in the latter field. The mines also contain much methane. In 1923 the tonnage from the Cahaba field was 2,966,505 tons of which 1,198,110 tons or nearly one half was from Bibb County, which lies to the extreme south.

**Tipple and Washer at Marvel. Alabama Mines Are Keen Advocates of Coal Washing**

As all the coal in the Cahaba and Warrior fields has its partings, washing of coal is the general practice. Much aggressive action has been taken. This washer has, for instance, both jigs and tables, the coal between  $\frac{1}{2}$  and 3 in. going to jigs and the still smaller coal being cleaned on the tables. The ash in the 1-in. washed slack and in the 3-in. steam runs from  $6\frac{1}{2}$  to 8 per cent.

windows and roofing, extra motors, spikes, nails, etc. During working hours a supply clerk is in attendance. Supplies are handled solely on presentation of written requisitions and a perpetual inventory is kept.

For the employees 305 dwellings, a 60x120-ft. store and two school buildings, one for white and one for colored children, are maintained by the company. The dwellings have running water and electric lights. The streets have been graded and covered with 6 in. of crushed sandstone and 3 in. of crushed slate from the company's rock-crushing plant which also furnishes crushed sandstone for concreting. All the overcasts in the mine are built of concrete. The stoppings are of brick. As many thousands of cubic yards of concrete have been used, a one-bag motor-driven mixer has been provided, as well as a one-third bag hand mixer for smaller work.

#### WATER SUPPLY OBTAINED FROM SPRINGS

For boilers and domestic supply, water is obtained from springs  $1\frac{1}{2}$  miles from the power house, the water for domestic purposes being stored in a 50,000-gal. concrete tank mounted on a 60-ft. concrete tower. Fire plugs and several thousand feet of  $2\frac{1}{2}$ -in. hose scattered around the town provide fire protection. Non-acid mine water is used in the washer, for strange to say the mine waters of Alabama are unusually free of acidity. A 400,000-gal. concrete-lined reservoir is used to store water for the washer, a 60,000-gal. reservoir provides the water for No. 2 boilers, and a 40,000-gal. reservoir that for No. 3 boilers. The outside water mains are of 4- and 6-in. bell-and-spigot pipe, and all the underground discharge lines are of 6- and 8-in. Universal pipe.

B. F. Roden is president of the company and the active superintendent of its operations. The mines are located on the Louisville & Nashville and Southern railroads.

#### Cauca Valley Coal Convenient to Panama

Four hundred and fifty miles from the Panama Canal in the Department of El Valle is the coal field of Cali, located in the Cauca Valley of the west coast of Columbia, only a few miles inland from the Pacific Ocean. It is connected with the port of Bona Ventura by the Pacific R.R. Cali is the capital of the Department of El Valle.

The region immediately surrounding this city is not well suited for mining, says the *Municipal Gazette* of Cali, but nevertheless its principal wealth consists of coal of which there are extensive deposits. The beds which have been discovered are on the western slope of the Andes Mountains and extend for a distance of more than 52 miles. There is every indication that other deposits exist in the neighborhood which will be exploited some day in the future.

The coal that is now being mined is a semi-bituminous fuel, having the following analysis: Carbon from 68 to 71 per cent; volatile matter, 23 per cent; ash, 5.4 to 7.6 per cent; sulphur, 0.8 per cent. Large quantities of coal are needed not only on the Panama Canal but at many points on the west coast of South America both for railroads and steamers. Practically only in Chile can any native coals be found on the market.

At the present time six coal mines near Cali are being operated, the aggregate production of which is about 3,000 tons per month. Nearly all of this is consumed by the Pacific R.R., the cost to that railroad being \$5.44 per net ton. This production is low because only rudimentary and costly methods of operation are employed, no new or modern machinery being used. With these installed all the steamers which run up and down the west coast of South America could be supplied with Cali coal, and it could be shipped to Peru, Ecuador and Chile, all of which offer a splendid market for this product.

## Engineers of Western Penna. Comment on Rock Dust

May Rockdusting Lawfully Replace Water  
Sprinkling?—Dusting of Shotholes—  
Getting Dust Into Aircourses

**A**T A well-attended meeting of the Engineers Society of Western Pennsylvania, Mining Section, on the evening of Nov. 24, in the William Penn Hotel, Pittsburgh, Pa., a paper on "Rock Dusting in Bituminous Coal Mines," was read by T. G. Fear, general manager of the Inland Collieries Co. Mr. F. A. McDonald presided, and in introducing the speaker said, "In the last fifteen years in this country 215 explosions killed 4,400 men. A thought of these catastrophes in itself is enough to drive any conscientious man to rock dusting."

"Aside from preventing coal-dust explosions, rock dusting," said Mr. Fear, "improves materially underground illumination; it lodges on wood timbers and makes them fireproof and to an extent, protects the roof from the slacking action of the air." Rock dust stemming is advocated in shooting, because it produces more lump coal, decreases smoke and suspends incombustible dust in the air at the instant when the danger is greatest that coal dust will be ignited by a blown-out shot. Of the particles of coal dust brushed from a timber set in the Indianola mine as much as 83.5 per cent pass through a 200-mesh screen. This indicates the explosive quality of the dust. It has been proved that average bituminous coal dust so long as it will pass through a 20-mesh screen is of an explosive character.

Basing his figures on his experience in the Indianola mine, Mr. Fear said a mine producing 61,000 tons of coal per month can rock dust at a cost of two mills per ton applying the dust three times a year; if the rock dust is applied four times a year the cost would be three mills per ton. (These figures apply only to the rock dusting of haulage entries, not aircourses, and assume that the rock-dusting program is well under way.)

In the discussion that followed, W. L. Affelder asked Mr. Fear if he sprinkled the Indianola mine with water before he started rock dusting. "Yes, extensively," said Mr. Fear. "How then," continued Mr. Affelder, "are you going to get around the Pennsylvania mine laws which specify in no uncertain terms that the mine must be sprinkled?" According to T. G. Fear, there must be a way around this difficulty. Illinois operators do not water-sprinkle rock-dusted areas. "Anyway," he interrogated, "isn't rock dusting sprinkling?" Mr. Affelder wondered what the defense would do if a state mine inspector would take a company to court that is rock dusting charging it with breaking the state mining laws.

Mr. Fear thought a state inspector would have no grounds for accusing a company of breaking the law but Mr. Affelder said the present mine laws of Pennsylvania were obsolete, and put the inspector, operator and miner alike in an extremely difficult position. Mr. Fear said that Secretary Walsh intended to endeavor to put a clause requiring rock dusting in the mine law at the next meeting of the state legislature. The Federated Engineering Society has appointed a committee to decide what shall be called standards in practice in rock dusting so that these might be utilized by the members of state legislatures in making mine laws.

A. R. Chambers, of the Michigan Limestone & Chemical Co., said that the cost of pulverized limestone, at the sending end is not high, but the railroad freight rates may be, and usually are. Marble dust has been shipped from Vermont into the Pittsburgh district, but the freight rates made delivery cost prohibitive. His company quarries limestone at the Port of Calcite, 200 miles north of Detroit and ships the screenings by water to Buffalo where they are pulverized and distributed.

Mr. Fear described one of his methods of getting dust on his aircourses. A hole is knocked into a stopping through which a 4-in. galvanized sheet-iron pipe is inserted. One end of this pipe is connected to the distributing machine and to the other end are attached 10-ft. sections of the same kind of pipe to give whatever length is desired. Short sections of automobile-tire inner tubes are sometimes used over the pipe joints. This method works quite satisfactorily.

In a single day twenty samples of mine dust can be taken and tested by the volumeter method to ascertain the percentage of incombustible material, said Mr. Fear. He recommends the use of rock-dust barriers on main return entries in addition to dust floated in on the air-current.

## Air Lift and Mines of Japan Interest Anthracite Engineers at Scranton

**A**T A MEETING held by the Engineers' Club of Scranton, Nov. 25, light was thrown on the unwatering of the Taylor mine and on the peculiar difficulties with which Japanese coal-mining engineers have to contend in their work, the papers being illustrated by lantern slides and diagrams.

Herbert Axford, formerly hydraulic engineer for the Glen Alden Coal Co., and now with the Ingersoll-Rand Co., read an interesting paper describing the use of the air lift at the Hampton Pumping Station of the Glen Alden Coal Co.

Last summer when the Lackawanna River broke into the Taylor mine the water completely submerged the Hampton pumps, located in the Clark bed, and also filled the Dunmore beds Nos. 1, 2 and 3 which are below the Clark.

There was no feasible way to get to the Dunmore beds and install pumps, therefore three air lifts were used. Two of these lifts discharged through 16-in. pipes and the third through a 12-in. pipe. Between April 30 and Aug. 14 these lifts raised 660,000,000 gal. of water from the Dunmore beds to the Clark bed where five 5,000-gal. per minute centrifugal pumps delivered the water to the surface.

J. W. White, manager of the Scranton office of the Jeffrey Manufacturing Co., spoke about his recent trip through the coal fields of Japan. Mr. White's story was well told. He spoke of his personal experiences inside and outside the mines. "Cheap labor and the employment of girls and boys in the mines prevent the extensive use of machinery in the mines of Japan," said Mr. White.

The high temperature—at places it is 90 deg. F.—and the dampness of the mine interior, often near the saturation point, make it extremely difficult to mine coal in Japan. Nearly all the mines are started from the outcrop and there are few mine shafts. One of the mines visited by Mr. White extended about three miles under the sea; another mine he saw has since become a geyser, boiling water now coming up the shaft.

## News Of the Industry

### Brophy Rejects Proposal to Adjust The Jacksonville Wage Agreement; Seeks Curb on Opening of New Mines

Flat refusal is the reply of the executive board of the United Mine Workers of district 2 to the recent letter of the Central Pennsylvania Coal Producers' Association proposing a readjustment of the Jacksonville wage agreement. The union officials disclaim the predictions of prosperity imputed to them in the communication from the operators and declare that the only solution of the problem brought about by the depressed condition of the coal industry in central Pennsylvania is "the development of new coal fields, and the opening of new mines must be checked until the demand and the supply counterbalance." The statement of the miners, which is signed by John Brophy, president; James Mark, vice-president, and Richard Gilbert, secretary, is as follows:

"Permit us to call your attention to the fact that you err in imputing to us the prophecy of 'prosperity' of which you speak in your letter of Nov. 7. To the *Coal Trade Journal* of Aug. 20 belongs that honor. The rôle of prophet has ever been assumed by the operators and not by the miners.

"For instance, in your statement dated April 2 you said it was agreed by many in the business that central Pennsylvania would not produce more than 15,000,000 tons throughout the coal year. However, up to Oct. 18, according to your own figures, we produced 30,670,782 tons.

#### Output Up Despite Gloom

"The *Coal Trade Journal* states on Nov. 12 that 'central Pennsylvania is sharing in the improved conditions in the industry in the country at large; that October loadings amounted to 66,782 cars, proving larger than anticipated and were the largest of the year except January.' Again in the same issue it says 'optimism prevailed in the country's bituminous markets during the past week' and that 'the consensus of opinion was that the next two weeks would see a marked increase in demand and that the worst was over.'

"These statements are more nearly in accord with the facts than such as have been issued periodically by the officers of your association ever since the present contract was signed on March 29 of this year. This contract your association signed voluntarily, yet the ink of the signatures was scarcely dry when you issued (April 2) a state-

ment which could have no effect other than undermining confidence in the contract.

"It is true that when you were questioned as to whether you would stand by the contract you stated (April 19): 'The present wage agreement for a period of three years will be carried out as faithfully by the operators as all preceding agreements.' Yet you have continued to issue from time to time statements carrying prophecies of practical ruin unless there were reductions. Is this an evidence of good faith on the part of the operators or is it an attempt to destroy the contract?

#### Trade Papers Optimistic

"It is true also that there is much idleness and slack work in this district. The miners feel it even more keenly than the operators. But it is not true that this district alone is affected, nor is it affected in greater degree than some of the adjoining districts. Even West Virginia, to which you constantly refer, has been and is far from operating steadily. If the optimism of the coal trade papers should be justified the condition of the industry would still be far from satisfactory because of the overdevelopment which makes slack work chronic.

"The solution you offer for the coal problem—a reduction in wages in this district—seems a simple one. But you are, or should be, just as fully aware of its real significance as are the miners. Should there be made in this district any wage concessions, the operators of all other districts signatories to the Jacksonville agreement would demand, and justly so, the same concessions. The non-union operators would promptly reduce wages still further, and the same relative positions between the districts would obtain. The only change accomplished would be that the miner would have still less money. There would be no more work.

"It is needless to say that District No. 2 is not willing to enter into a competitive wage war which could bring nothing more than increased poverty and desolation to the miner and his family. The early history of this district is replete with wage wars, and the results were always the same—added poverty and suffering for the miners and consequently their communities, and no gain for the operators. It is only since the wage contract has checked cut-throat competition that

#### Will Use Sulphur Gas To Make Ghost Walk

Men of the Coalton mine, at Nokomis, Ill., are looking for a supposed ghost which they say they have seen and that may be the cause of strange lights that appear and suddenly disappear around the mine. St. Louis detectives are looking for Frank Deverick, a former employee of the mine, who is alleged to have stabbed a companion to death in a St. Louis drinking party last spring. Deverick has not been seen since the tragedy and miners of a superstitious nature are inclined to think he may be dead and his spirit hiding in the mine. Officials of the mine are planning to use "sulphur gas" to smoke the ghost out.

even the slightest stability has been known in the coal industry.

"We, the Executive Board of District No. 2, therefore, reject as unsound your solution of the coal problem.

"You ask us what suggestions we have to make to relieve the union miners, the union coal operators and the business interests of the communities in which we reside.

"We reply: The nation consumes only enough coal to supply her needs. Were the miners to produce without pay coal in excess of that amount, the consumption would not increase. We are now supplying sufficient coal to meet all demands, yet work is slack and idleness is widespread in all bituminous districts. This is because there is a large overdevelopment in the coal industry.

"There is only one solution to this problem—the development of new coal fields and the opening of new mines must be checked until the demand and the supply counterbalance. Until this is done and not until then can you hope for substantial, permanent improvement in the bituminous coal industry."

Coal to the extent of 253,612 tons was used in the manufacture of explosives during 1923, according to figures issued by the Bureau of the Census. Similar figures on other industries are as follows: Coffins, burial cases and undertakers' goods, 78,503 tons; nets and seines, 2,833 tons; glass cutting, staining and ornamenting, 14,818 tons; china decorating, not done in potteries, 1,111 tons; sporting and athletic goods, 25,861 tons; straw hats, 21,647 tons; feathers and plumes, 291 tons; professional and scientific instruments, 24,288 tons.

## Mayor Hylan Warns Against Coal Gougers in New York

To prevent suffering and discomfort among the poor of New York City this winter through lack of coal Mayor Hylan directed Health Commissioner Monaghan on Nov. 27 to take the usual steps to see that the poor receive coal this winter and that they are not made the victims of profiteers. The Mayor wrote:

"The cold weather, bringing greater demands for fuel, is the open season for profiteering by unscrupulous retail coal dealers. I feel that the Health Department could help considerably by a check-up of the retail coal dealers in this city, particularly the so-called cellar men. We have heard of no particular shortage of anthracite coal this year, but this is not likely to deter some of the retail dealers from charging exorbitant prices.

"The Mayor's Committee of Women have been carrying on splendid work for the last seven years, issuing priority tickets to the poor and insuring the delivery of small quantities of coal for home purposes. Their work of distribution would be greatly aided if there were some assurance that a proper supervision and regulation were maintained over prices. The Health Department might very properly undertake this work and call upon any other commissioner or department, such as Commissioner O'Malley of the Department of Public Markets, to help in the stabilization of the price of coal.

"Will you, therefore, proceed at this time to make such arrangements as will tend to prevent profiteering in this essential commodity so that the people who must depend upon the purchase of small bags of coal from cellar men and other dealers will not be forced to pay an excessive price to keep from freezing during the winter months."

## Speed Return of Empties To Avert Car Shortage

Traffic officials of the various mining companies on the Louisville & Nashville Ry. system have been meeting with officials of the road to work out a helpful system of routing that would cut down the time on the return of empties for renewed service—this in view of obviating to the fullest extent possible car shortage during the winter. The plan is to leave intermediate routing open whenever possible and let the main routing take the course that will get the car home quickest.

## More Coal Being Stored, Say Purchasing Agents

Notwithstanding the feeling in the coal industry that consumers were not storing coal during October, according to the monthly survey of the National Association of Purchasing Agents the amount of hard and soft coal in the bins of industrial consumers on Nov. 1 was 77,754,054 net tons as compared with 52,458,736 tons on Oct. 1, a gain of 25,285,343 tons. The survey shows that consumption during October increased by more than 1,200,000 tons over the September figures, the reports showing that the larger concerns are using more coal and the smaller firms an even greater increase than in September.

For heating industrial buildings during October the coal used was about 300,000 tons greater than in September.

It is estimated that on Nov. 1 there was sufficient coal in the hands of industrial users to last 66 days, based on the average daily consumption for October.

## Alberta Coal Probe Halts for Collection of Data

After having been in session for a week, the commission recently appointed to make a survey of the coal industry in Alberta has taken one week's recess pending the arrival of certain information from various points in eastern Canada, the United States and England where similar investigations have been conducted in former years. According to H. M. E. Evans, chairman of the commission, there is much preliminary work to be done and non-contentious material to be gathered before witnesses will be heard, but it is hoped to begin taking evidence within a few weeks.

Broad powers have been conceded to the commission for the purpose of collecting accurate information in regard to every branch of the coal industry and these powers will be utilized to the full, it is announced. The scope of the inquiry, according to the original motion passed in the Provincial House last March, will include wages, housing conditions, profits made by companies, coal reserves, systems of mining, grading and inspection and all matters relating to marketing. This latter clause probably will include the matter of the Ontario and Manitoba markets for Alberta coal.

Owing largely to the big railway contracts having been postponed, production is slow among the steam coal mines in the province though the domestic mines are all working steadily. The Mountain Park Colliery has closed down until January, causing much distress among the miners who have been idle all summer owing to the strike. Other mines are working only short shifts until more orders can be obtained.

Prospects for next year, however, are bright and at least one company, the Luscar Collieries, Ltd., is preparing for an increase of business. A modern steel tippie capable of handling an output of 2,000 tons every eight hours is in process of erection in addition to a box loader, a new power plant and an extension to the siding.

## Hayes Loses \$35,000 Suit to Vinton Collieries Co.

An echo of the miners' strike of 1922 in the central Pennsylvania coal field was heard from New York on Nov. 24, when Arthur Garfield Hayes lost his suit in court there against the Vinton Collieries Co., of Vintondale, Cambria County, for \$35,000 damages for alleged false arrest. Hayes was a prominent figure in the 1922 strike and a leader of the miners. When he attempted to hold a meeting in Vintondale he was placed under arrest and fined by a local justice of the peace. Returning to New York he entered suit against the collieries company, alleging false arrest and invasion of his constitutional rights. The case was tried before Judge Franks, who directed a verdict for the defendant company on several counts, passing several others to a jury for determination. The jury held the collieries company not guilty and the case was dismissed.

## New Englanders Inspect Virginia Coal Mine

Some of the twenty New England business men who toured Virginia last month in the interest of commercial reciprocity, just before being taken in mine cars to inspect the Derby Shaft in southwest Virginia. The trip was arranged by the Virginia State Chamber of Commerce in the interest of closer trade relations between the mining interests of Virginia and the big consuming centers of the East and North. On the right hand side, sitting in the first car, are Dr. Joseph H. Smith, president of the Virginia State Chamber of Commerce; Clifford S. Anderson, president of the Associated Industries of Massachusetts; John W. Bray, general sales manager of the Bullard Machine Tool Co., of Bridgeport, Conn.; Romeo W. Miller, of the Bridgeport Crane Co., and Lee Long, vice-president of the Clinchfield Coal Corporation.

## Rate Cut to Northwest in Effect Soon; Will Adjust 15c. L. & N. Differential

An agreement was reached before the Interstate Commerce Commission in Washington, Nov. 26, between representatives of the Norfolk & Western, the Chesapeake & Ohio and the Louisville & Nashville whereby the tariffs on coal for the Northwest which were to have become effective Dec. 5 and 6 will be withdrawn, but the lower rates to the Northwest will go into effect. The tariffs are to be withdrawn so as to allow an adjustment of the 15c. differential which the Louisville & Nashville has enjoyed.

Representatives of the Western lines came home from Washington to carry out the positive suggestion made by the commission that they check out a new basis for joint through rates from Eastern mines to destinations in Western Trunk Line Territory. This rate check was to be held in Chicago Tuesday, Dec. 2. These new rates will be predicated to a large degree on the \$5.40 rate the commission found reasonable for L. & N. coal to the Twin Cities. This means that rates on eastern Kentucky and West Virginia coal will without doubt be somewhat increased to destination points on the Minneapolis & St. Louis, the Chicago Great Western and the Wabash, which previously have been enjoying low L. & N. joint through rates, but will be decreased on other lines. The exact method of determining these new rates has not been determined.

## Instructive Program Planned For Engineers' Meeting

A program to aid the engineer in solving his problems, especially that of trimming operating cost, has been arranged for the fourth annual convention of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, to be held at the Frederick Hotel, Huntington, W. Va., Dec. 12 and 13.

The two-day meeting will open Friday morning, Dec. 12, when F. M. Reigher, electrical engineer, American Coal Co. of Allegheny Co., Bluefield, W. Va., will present a paper, "Rotary Converters as Compared with Motor Generators." Another comparison will be made by N. A. Johnson, chief electrician, Buffalo-Eagle Coal Co., Brae-holm, W. Va., who will discuss "Anti-Friction Bearings as Compared with Plain Type Sleeve Bearings for Mining Machinery." The remainder of this session will be devoted to open discussion on the following questions: "What Can Be Done to Prevent Theft of Rosettes, Lamps and Cord?" "How Should Mine Foremen Co-operate with Mine Electricians so That Both Can Be of Most Value to Their Company or Employer?"

In the afternoon meeting, Byron B. Minnium, of the Electric Storage Battery Co., Cincinnati, Ohio, will discuss "Voltage Control in Mines by Use of

John J. Lincoln

Treasurer, Pocahontas Coal Operators' Association, and general manager, Upland Coal & Coke Co., Elkhorn, McDowell County, W. Va.

Storage Batteries," and F. A. Singer, electrical engineer, Southern Mining Co.'s Interests, Williamsburg, Ky., will describe the "Electrical Department Methods of the Southern Mining Co."

The problem of trimming operating cost will be tackled in the Saturday morning session by J. H. Edwards, electrical engineer, associate editor, *Coal Age*, Huntington, W. Va., who will present a paper: "Reducing Cost by Proper Supervision of Mechanical and Electrical Equipment." After Mr. Edwards' talk the following questions will be presented for open discussion: "How Should Feeders Be Installed in Boreholes?" "What Important Repair Jobs Are Being Done by Electrical Welding?" "How Should Carbon Brushes Be Applied to Flush and Undercut Commutators?" The regular business meeting will conclude the morning program. In the afternoon the members of the association and their friends will inspect industrial plants of interest.

## New York Coal Exporters Charge Alien Plot

J. W. Stinson, attorney for Gano, Moore Co., coal exporters, of New York City, alleges that alien interests inspired the complaint of the Federal Trade Commission against the firm in a reply to the commission Nov. 25. Such aliens now are engaged in litigation with his clients, Mr. Stinson declared, and for that reason he contended that the commission is without authority to institute investigation "upon information or complaint of aliens in company with persons represented to be the friends of agents or of counsel of the commission, but in fact the undisclosed legal representatives of such aliens."

The commission's complaint had alleged that the Gano, Moore Co., Gano Moore Coal Mining Co., and M. Rea Gano, their president, violated contracts for the sale of coal to purchasers in Argentina, by delivering coal of an inferior quality to that specified, or failing to make deliveries of the proper quantities, under the contracts, "thereby tending to bring into disrepute and injuriously affect the entire exporting trade of the United States with and into the Argentine Republic."

Referring to a statement in the complaint that the United States has about three billion dollars invested in the merchant marine and that millions of dollars annually are appropriated out of the public treasury for the purpose of retaining and extending foreign commerce and trade, the Gano, Moore Co.'s attorney denied that this is relevant to the complaint and further denied influence arising from this allegation.

Wilful or negligent default from the terms of the contracts with Argentine purchasers also was denied on behalf of the respondents, and none was admitted except such as were beyond their control. "Full, reasonable and substantial performance ultimately has been given notwithstanding such circumstances and heavy loss to the respondents in pursuance of contracts whose mutual consensus imposes still unfulfilled obligations upon the purchasers," the commission was informed.

## Hoover Asks Clear-Cut Ruling on Activities of Trade Associations; Reviews Work of His Department

Herbert Hoover, Secretary of Commerce, in his annual report, made public Nov. 27, appeals for clarification of the laws affecting trade association activities.

"It is imperative," said the Secretary in referring to trade associations, "that some definition should be made by which an assurance of legality in proper conduct can be had and by which illegality or improper conduct may be more vigorously attacked.

"Any collective activity can be used as a smoke screen to cover conspiracy against the public interest, but that is no reason for condemning all collective activities. Just because automobiles are sometimes used by bootleggers for the illegal transportation of liquor we do not prohibit their manufacture or their use."

Elimination of national waste is urged by Mr. Hoover. Under this heading he reviews the accomplishments of the department during the first three years of the present administration, notably in the field of unemployment, seasonal construction, coal, superpower, standardization, simplified practice, co-operative marketing and the reduction of housing costs.

### Trade Bodies Cut Waste

In the section of the report dealing with trade associations Mr. Hoover says:

"One of the most important agencies through which the elimination of waste may be promoted is the trade association. It is true that a small minority of these associations have been in the past used as cloaks for restraint of trade by such activities as open-price associations and other attempts to control distribution or prices. It is equally true that the vast majority of trade associations have no such purpose and do no such things. The dividing line, however, between what activities are in the public interest and what are not in the public interest is not today clearly defined either by the law or by court decision.

"In consequence of recent decisions of the courts many associations are fearful of proceeding with work of vital public importance, and we are losing the value of much admirable activity. At the same time we are keeping alive the possibility of wrongful acts."

Turning to the bituminous coal industry the report says that investigations made early in the present administration revealed the high instability of this industry and the fact that it was functioning at great national loss. Of accomplishments in this field Mr. Hoover says:

"Through co-operation of trade associations of the principal industrial consumers, through chambers of commerce and public utilities a large amount of regular summer storage has been induced. Through the fine co-operation of the railways greater equipment and terminal facilities have been provided and car shortages have been largely

eliminated. Through co-operation by the department with the unionized operators and with the leaders of the United Mine Workers a long term agreement has been entered upon, which insures industrial peace in the industry."

The program of the Northeastern superpower committee, under Mr. Hoover's chairmanship, is discussed as another effort in the direction of waste elimination.

### Mine Guard System Enjoined By West Virginia Court

An injunction against employment of "mine guards" by Don Chafin, Sheriff of Logan County, West Virginia, was issued Nov. 22 by Judge A. P. Hudson, of the Kanawha County Circuit Court.

Besides Sheriff Chafin, the injunction is directed against Circuit Court Judge Robert Bland, of Logan; Prosecuting Attorney John Chafin, of Logan; W. F. Farley, Johnson Queen and P. M. Toney, the Logan County commissioners; C. L. Estep, Assistant Prosecuting Attorney, approximately 250 deputy sheriffs and about 50 Logan County coal companies.

The order restrains the Sheriff, County Court and other officials from appointing deputies to act as watchmen for private individuals or corporations, and restrains the coal companies from paying money directly or indirectly to the deputies for any services to coal companies or to Sheriff Chafin.

### Indiana Consolidation Talk Is Revived

The long-discussed movement to consolidate the coal mines of District No. 11, which includes the entire Indiana bituminous coal field, is being considered again by the coal operators about Terre Haute. Reports of such a movement have been current for several months, but it is evident that the effort has been somewhat accelerated recently by the general hard time which the whole state has met.

The plan is said to provide for the consolidation of all the shipping mines in the state, numbering approximately 125, and is considered with the view to reducing the cost of production and thereby arming the industry in the state with more power and ability to meet competition, which it seems it is utterly unable to do at the present time.

"I have no definite knowledge regarding such a movement," said Phil. H. Penna, secretary of the Indiana Bituminous Coal Operators Association, "but I do know in a general way that the consolidation of the mines of the Indiana field, or perhaps the forming of several consolidations, is being considered by some of the operators. The plan is very desirable, and must be effected if we expect to remain in business."

At present the Indiana mines are producing only about 35 per cent of their potential capacity. Every oper-

### Lewis' Strength Slipping In West Kentucky

It is reported from Central City, Ky., that the Oakland Coal Mining Co., which had been operating in a limited way for a week or so on the 1917 wage scale, succeeded last week in getting its workers to sign up on a local union basis, the men breaking away from the United Mine Workers, as was the case in Webster, Hopkins, Union and Henderson counties. In the Muhlenburg County field, around Central City, the Oakland is the first mine to operate since April 15. The Gibraltar Coal Mining Co. has been cleaning up and getting ready to operate and others probably will start soon, which makes it appear as if the régime of the United Mine Workers in western Kentucky is nearing an end.

It is reported that more than one hundred men started work for the Oakland company last week.

ator is continuing with the hope that conditions will improve. Under a statewide consolidation a great many mines not being operated at present and which are a burdensome expense would be abandoned or indefinitely closed, and only those mines which are necessary to supply the demand would be operated. Co-operative buying and selling would be counted on to reduce expense.

Two similar movements toward consolidation have been talked of in the Illinois mining districts, according to reports received in Terre Haute. Thirty-five mines in the Belleville district are said to be involved in one negotiation and the other scheme includes a number of operations in central Illinois.

### Orders Pittston Strikers to Work or Lose Charters

Scranton, Pa., Dec. 2.—D. W. Davis, international organizer of the United Mine Workers, yesterday called a meeting of District 1 executive board, at which it was decided to give the 12,000 miners of the Pennsylvania Coal Co. engaged in an outlaw strike until Wednesday to return to work before revoking the local union charters.

John L. Lewis, international president of the mine workers, evidently has become weary of complaints from anthracite operators that the contract between the operators and the union is being continuously broken by unauthorized strikes over alleged grievances. He evidently suspects what is taken for a general fact in the anthracite region, that the strikes are just as much a piece of union politics against the presiding district officials as a protest on conditions at the mines. Lewis' attitude was expressed late last week in a telegram ordering the district officials to turn over their problems to Mr. Davis, an Illinois man.

What attitude the Pennsylvania Coal Co. strikers will assume in face of the threat issued by the district board remains to be seen, but it is not expected to bring the strike to an end.

## Program to Eliminate Waste of Wood May Presage Better Mining Methods

Coal Industry Encourages Plan to Conserve Forest Products—Decline  
in Use of Wood for Fuel Promises New Outlet for Coal—  
Economies in Improved Machinery

By PAUL WOOTON

Washington Correspondent of *Coal Age*

The Washington conference on utilization of forest products emphasized the fact that the coal industry has a selfish as well as an altruistic reason for encouraging the research program which aims to eliminate waste of wood. This includes, of course, the utilization of waste for higher purposes when that is possible. The time practically is past when any large portion of so-called forest waste is burned simply to get rid of it. Large amounts of it, however, are being used as fuel.

Higher uses, it was contended at the conference, can be found even for sawdust. Wood fiber lends itself admirably to the making of paper. It was revealed at the conference that a means has been perfected whereby the less valuable American hardwoods can be converted into newsprint paper, a product for which our requirements are large and which now is largely imported. The manufacture of kraft paper from Southern pine of itself in recent years has become a great industry. With the use of paper packing boxes becoming general a great market is being established for container board. The insulating properties of dead air cells have even built up a market for "synthetic" lumber, which consists of boards rolled from a pulp made from timber waste.

The advance already made along these lines, with the comprehensive research program now planned, promises to reduce still further the amount of wood available for the production of energy and heat. Many overlook the extent to which wood is a competitor of coal. In 1922, according to Forest Service figures, 100,000,000 cords of wood were used by the United States. This is equivalent to 60,000,000 tons of coal.

### Much Wood Still Used as Fuel

Sight frequently is lost of the fact that wood was the principal fuel in the United States until 1880. In that year 140,000,000 cords were used, or the equivalent of 90,000,000 tons coal. In the forty-five years since that time it has held on tenaciously and, as stated, still is displacing coal to the extent of some 60,000,000 tons. For the reasons mentioned, however, a much more rapid decline in its use may be expected in the future with something of a windfall to the coal industry, which eventually will absorb most of the 60,000,000 tons—an item of new business which will not be sneezed at.

In the whole forest products conference there was much of interest to coal, in that the steps now being taken to conserve wood eventually will be taken to conserve coal. In its development coal is a generation or more behind the lumber industry. A genera-

tion or two ago forests were so extensive that waste came in for little consideration. It was induced on every hand by cutthroat competition. Some of the very men who had no patience with the Roosevelt-Pinchot plea for conservation, voiced in 1907, were leaders in this recent forest products meeting and are strongly behind the conservation of our forest resources from the trees in the woods to the use of the board by the carpenter who nails it in its final place. They even went further and are urging that the board be protected from decay after it has been placed in final use.

Coal operators in their present state of mind have no great interest in preventing wastes in mining or other avoidable losses, particularly if it adds anything to the cost of production, but if forest products furnish a proper criterion the day is not distant when more is going to be heard of the elimination of waste in coal.

### Economies of Machinery

A union in the height of its power might block a move to utilize roof coal in the Pittsburgh bed, but it might be more conciliatory today when the Pittsburgh operators are so hard pressed in the competitive struggle. The common defense of waste in mining is that the competitive situation is such that full utilization of mine resources is not practicable. It is certain that definite limits exist as to the amount of coal which can be mined, but by using the latest mechanical appliances, under close supervision, it is known that much less coal can be left unmined than usually is the case. Not only that; it has been demonstrated that such a course results in economies which before had not been considered.

Employment of mechanical equipment in the larger scale operations cuts down the time required to work out a given area and reduces the fracture caused by subsidence. The coal industry has not reached the point where it is catching at every straw that suggests an opportunity to lessen waste, but if experience in the lumber industry is duplicated each passing year will see more and more pressure brought to save the maximum amount of a great resource.

### Systematic Research Advisable

In fact the coal industry might be forewarned by the experience in some other industries and undertake more systematic research before such a program is forced upon it. The nitrate producers of Chile, for instance, have gone along blithely for many years mining their product in an antiquated manner and with little regard for the economies of better practice. The synthetic nitrogen industry began to

## Ford Moves Coal Records By Wagon Train

Although Henry Ford, the flivver king, has built millions of automobiles and has money enough to command any known means of transportation, when he found it necessary to move the records of the Fordson Coal Co. from the Redbird operation at Pineville, Ky., to the little community of Annalee, in the heart of the Cumberland Mountains, he had recourse to a wagon train to negotiate the twenty miles.

Whether the transfer meant the early opening of Ford holdings in the mountains could not be verified by officials, who said the move had no special significance.

The equipment will be taken to Garrard Station by train and then loaded on a wagon for the twenty-mile trip over the trail to Annalee.

There has been much talk of a railroad to be built by the Ford interests into the heart of the mountain properties, but these reports have always been denied by those in authority.

develop. It had a small beginning and its growth has been at isolated plants scattered throughout the world. The Chilean producers gave little heed, as they felt certain no manufactured product could compete with a great natural resource. Within a year, however, they have been confronted with an aggregate production from many small plants which has cut heavily into their market. At a meeting of these producers in Chile recently the situation was appraised in its significance and a pretentious research program authorized. This is only one example of a general trend. Even industries that are not hard pressed are finding that investments in research pay big dividends.

## Nova Scotia Miners Prepare To Demand Higher Wages

Wage demands to be made by the executive officers of District 26, United Mine Workers (Nova Scotia), in negotiating with operators for a new agreement were decided upon at the miners' convention at Sydney, N. S., on Nov. 21. They will ask 25 per cent increase for datal men, 10 per cent increase for contract workers; 10 per cent additional increase for all miners working on night shift or two-shifted places, and a 15 per cent increase for all three-shifted places. The opinion expressed during the discussion was that companies should do away with the double and triple shifts and that the only way to effect this was to force up operating costs by demanding high wages for the men employed in these places. The convention adopted a resolution to the effect that the Executive Board use its influence with the British Empire Steel Corporation and the Department of Mines to have all mines now working continue to operate, failing which "direct action" will be taken by the district.

## Practical Pointers For Electrical And Mechanical Men

### Explosion Cannot Injure This Mine Fan

Weak Section Built in Air Duct Acts as Safety Valve  
—Auxiliary Doors Cover Blown Out Section in Air-  
Way and Ventilation System Is Quickly Restored

Records compiled by the U. S. Bureau of Mines show conclusively that in the event of an explosion or mine fire, if the fans can again be quickly put in service, damage to the mine and injury to the workmen may be greatly reduced.

At the J. K. Dering Coal Co. mine near Eldorado, Ill., an old hoisting shaft is now used as an airway. The fan house is built adjacent to the old shaft, and a concrete duct connects the fan to the shaft. An interesting feature about this airway is that part of it is constructed of light wood boards which have been covered with a thin layer of cement to make them airtight. Should an explosion occur, this section is expected to act as a safety valve. The force of the explosion will probably blow out the boards and thus relieve the fan from the full force of the blast.

In such an event, if it is desirable, as it usually is, to get the fan in operation, the auxiliary sheet-iron doors hinged to the edge of the weak section in the airway, which have hitherto been left open, may be closed, repairing the breach that the explosion has caused. The facility with which this operation can be performed makes this provision of unusual value. The illustration shows a diagrammatic sketch of the airway, fan and airshaft. Fig. 1 shows the doors raised for the purpose of ex-

Fig. 2—Mine Fan with Relief Section

An explosion in the mine ventilated by this fan would no doubt blow out the weak section of the air duct, which has been arranged to relieve the fan of the full force of the explosion.

hibiting their location on the fan duct. It is possible to close both of these doors just as soon as any part or the whole of the weak portion of the airway is blown out.

### Portable Pipe Vise, Another Time Saver

Running conduit in a breaker may be made a hard job or an easy one according to the way in which it is handled. At Hazleton Shaft Colliery, of the Lehigh Valley Coal Co., new

construction made necessary the tearing out of some of the old lighting lines faster than replacements could be made. The need for lights made it essential that the work be speeded up, and the question was raised as to the cause for the slow progress.

An investigation located the trouble easily. The method previously used was to strap a pipe vise on whatever beam was handiest. As the conduit line advanced, the vise had to be moved to another beam and fastened to it. This consumed much time, because, if there was no beam handy, the vise had to be taken back to the old set-up which in some cases was some distance away. More than once the vise disappeared over night or over the week end, because being so readily portable someone had borrowed it and then had failed to put it back in its place.

In order to avoid these difficulties, a sheet-metal body was constructed ar-

### Portable Pipe Vise Easily Made

All the necessary fittings for a conduit construction job are carried with this one-man vise and stand.

ranged for the reception of four pipe legs. The pipe vise was permanently mounted on the top of this body, forming a portable, one-man equipment, complete and ready to be set up anywhere desired. Underneath the vise is a pocket which holds a collection of conduit fittings, a can of white lead, pipe straps, nails, etc., necessary in making a conduit installation. When the vise is moved, the small tools and parts are carried with it.

The sketch gives a fair idea of how this handy tool was constructed, and anyone who can make use of the contrivance is welcome to build one like it.

Hazleton, Pa. JOHN FRANCIS,  
Electrician.  
Employees' Magazine Lehigh Valley Coal Co.

Fig. 1—Sheet-Iron Fan Doors Ready to Be Closed

By closing the sheet-iron doors the damaged part of the airway may be quickly sealed off and the fan started after an explosion. Even greater protection would have been afforded had a somewhat larger weak section been placed in the direct line of the shaft. Probably some reason not apparent prevented a choice of this position.

## Put Sand in the Boxes and Not in the Bearings

Sand, dust and dirt cause more damage to bearings in a few minutes than months of ordinary wear. Mine locomotives are built close to the ground, and consequently axle bearings and motors soon become covered with dirt and fine road dust.

Even though it is necessary to sand mine rails, the practice has its disadvantages. The sand is easily picked up by the motor wheels and dropped on the bearings. However, this cannot be avoided, but with care the sand that usually enters the bearings when the sand boxes are being filled can be prevented from so doing.

At some mines an extra supply of sand is carried on the locomotive so that if the sand boxes are emptied they can be promptly filled even though the locomotive may be a long distance from the sand bin.

### STOP LEAKAGE OF SAND

Sand which is carried on the top of a locomotive sooner or later leaks and gets into the bearings. Therefore, this practice should be discouraged.

**Handy Scoop Prevents Sand from Spilling on Bearings**

It is easy to shoot sand into locomotive sand boxes when this device is used. Sand that gets into the bearings grinds them out and increases maintenance costs.

On some locomotives the holes for the sand boxes are so located that it is difficult to fill them without spilling sand on the ground or on parts of the locomotive. The sketch shows a handy scoop with two handles. This accessory makes it easy to dig into the sand pile and facilitates filling the boxes. It is both a bucket and a chute, and when used prevents sand from getting in the axle bearings.

## Battery-Locomotive Meter Put in Negative Line

Trouble with ampere-hour meters on our combination battery-and-trolley locomotives has been greatly reduced by a simple change in the wiring. These locomotives are equipped with 180-volt motors which are supplied with 250 volts when operating from the trolley and with 125 volts when operating from the battery. The change from one voltage to the other is made by connections on the reverse cylinder of the controller. The fact that these are combination locomotives makes it necessary to have the negative wiring grounded to the frame as with the ordinary trolley-type locomotive.

As originally received these locomotives had the meter connected in the positive side of the battery circuit.

This arrangement, together with the permanent ground of the negative to the frame, caused a difference of potential between the wiring in the meter and the meter case of 100 to 150 volts. It frequently happened that the meters were severely damaged by arcs to the ground, the arcs generally being caused by the meter cover while being removed coming in contact with the meter windings. Changing the wiring so as to place the meter in the negative line, has entirely eliminated this trouble.

### CHANGED ORIGINAL CONNECTIONS

The original wiring is indicated by the full lines in the accompanying drawing. The scheme of the revised wiring, placing the meter in the negative, is indicated by the additional dotted lines and by the marks X which denote that certain wires were cut.

### Meter Shifted to Negative Line Prevents Damage

To make this change required cutting the old wiring in three places, shown at X, and making additional connections illustrated by the dotted lines. Now the difference of potential between the meter circuits and the meter case is so low that insulation breakdowns and short circuits are almost impossible.

Before the change an average of six meters per year, from the five combination locomotives in use, were damaged by grounds. The position of the meters was changed to the negative conductor over two years ago and since that time not one of the meters has been damaged by grounding or internal arcing.

## How to Weld Cast Iron with A Self-Fluxing Electrode

An electrode has been devised by the General Electric Co., and will be described in the New Equipment section soon, which consists of a metal core surrounded by a suitable coating of flux, the whole being provided with a sheath so that the operative has in the metallic rod all the material for the making of the weld except the torch and tanks. The method of using such electrodes is as follows:

(1) The electrode should be held at right angles to the work, maintaining a short arc, except when it is difficult to fuse the metal properly, which is due to what is commonly called a hard or sandy condition in the base stock. When this occurs the arc should be lengthened temporarily to afford the desired fusion.

(2) The arc should travel in a direct line along the seam when welding thin parts, and be moved back and forth across the joint on heavier parts. The arc should never be vibrated or weaved to and fro as is the practice when using ordinary base electrodes.

(3) The fact that the welding electrode fuses more rapidly than other electrodes should not encourage rapid travel. Slow travel tends to avoid rapid cooling and thus produces softer and sounder welds. The flux coating deposited by the electrode also materially assists in retarding the rates of cooling.

(4) Where practicable, the weld should be completely filled in one continuous deposit rather than in successive layers. In welding heavy V'd parts, the V should be completely filled from bottom to top during the advance along the line of the weld.

(5) To insure against slag inclusions, any accumulations of flux scale may be occasionally removed, although thin layers of this scale are easily fused and float to the top with the slow travel of the arc.

### Current Values for Various Sizes of Electrode

Diameter Electrode in In.	Current in Amp.	Diameter Electrode in In.	Current in Amp.
$\frac{3}{8}$	50	$\frac{3}{8}$	140
$\frac{1}{2}$	Up to 110	$\frac{1}{2}$	180

Suitable current values for the various sizes of electrode are given in the accompanying table. For some purposes current values greater than those herein mentioned may be used to advantage.

# Production And the Market

## Spottiness Characterizes Soft-Coal Market; Anthracite Business Easier

Spottiness continues to characterize the coal business of the country. A taste of winter weather in the Middle West has given stimulus to domestic demand, but the supply is more than sufficient to meet all requirements. In Kentucky and Ohio, however, a return of mild temperature has brought about a weakening tendency, which has been intensified by the virtual close of lake shipping. There is a slight improvement in West Virginia for both steam and domestic grades. The Pittsburgh market has sagged again after several weeks of gradual upturn. The Atlantic seaboard as well as the Southwestern markets are holding to a fairly even keel, marked neither by high lights nor dark shadows. New England is in the throes of a dull period from which there is no immediate prospect of relief.

In most sections steam coal is moving largely on contract, and consumers are taking comparatively small quantities. Those not parties to agreements are jogging along on the old hand-to-mouth scheme, reassured by the weather, the volume of output and continued good performance by the railroads. Despite the heavy grain movement there has been practically no car shortage, but some easy-going consumers may have overlooked the developments that probably would follow in the wake of a snowstorm or a real cold wave.

### Anthracite Business Featureless

A somewhat complacent attitude marks the anthracite trade, consumers being disposed to take things easy. Shipments have been irregular because of intermittent outlaw strikes at the mines, but independent quotations have not been much affected. In general the call for stove has been in excess of the supply, though Philadelphia shows a preference for nut. Egg moves only moderately well, but pea is sluggish. Steam coal shows medium activity, buckwheat being somewhat improved and rice and barley a little easier.

Coal Age Index of spot prices of bituminous coal

advanced one point last week, standing on Dec. 1 at 171, the corresponding price for which is \$2.07.

A pronounced slump marked activity at Hampton Roads last week, dumpings of coal for all accounts for the seven-day period ended Nov. 27 totaling 299,555 net tons, compared with 369,793 tons the week before.

The lake navigation season practically came to an end last week, when dumpings at Lake Erie ports up to and including Nov. 30, according to the Ore & Coal Ex-

change, were as follows: For cargo, 562,467 net tons; for fuel, 20,802 tons, compared with 704,930 and 28,698 tons respectively during the preceding week.

There is not much change in the daily rate of production of bituminous coal, for although the total output for the week ending Nov. 22, according to the Geological Survey, was 10,588,000 net tons, an increase of 459,000 tons over the preceding week, the lower figure for that week was due to the partial observance of Armistice Day. It is interesting to note, however, that this is the second time that output has exceeded that of the corresponding week of 1923. Anthracite production in the week ended Nov. 22 totaled 1,827,000 net tons, compared with 1,674,000 tons in the previous week and 2,031,000 tons in the corresponding week of last year. Local strikes have been limiting hard-coal output.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
Nov. 8.....	10,726,000	9,331,000
Nov. 15 (a).....	9,717,000	10,129,000
Nov. 22 (b).....	10,160,000	10,588,000
Daily average.....	1,693,000	1,765,000
Cal. yr. to date (c).....	495,428,000	413,574,000
Daily av. to date.....	1,795,000	1,498,000

#### ANTHRACITE

Nov. 8.....	1,903,000	1,592,000
Nov. 15.....	1,669,000	1,674,000
Nov. 22.....	2,031,000	1,827,000
Cal. yr. to date (c).....	84,424,000	81,227,000

#### COKE

Nov. 15 (a).....	254,000	149,000
Nov. 22 (b).....	257,000	158,000
Cal. yr. to date (c).....	16,640,000	8,608,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Is Colder Now

Some improvement in a sagging domestic market was felt throughout the Midwest during the week because of the snappy weather. There were no price changes worthy of note, however, except in Standard screenings because the supply always is so ready to meet and overwhelm the demand. This situation explains why not all the lump and egg coal standing unbilled on wheels in Illinois and Indiana has been shipped. Steam business throughout those two states is only fair. Too many mines have reopened lately for the good of the market.

Railroad business from Illinois mines is easy, a few roads taking a little coal. Strip mines continue to show good production and are selling at what the market will bring and usually are in competition with the low prices of the non-union west Kentucky field. Cars are plentiful and mines are getting from two to four days a week.

Mt. Olive is still slow in domestic and mines are getting but two and three days a week; those working three are loading railroad coal. Steam is going mostly on contract. In the Standard field there has been an advance in the price of screenings, which is now \$1@1.15. Everything else from that field is dragging.

Seasonable weather in St. Louis has created a little domestic demand for middle grade coal. The weather as yet has not brought the demand for Standard that it will later.

There is practically no anthracite, smokeless or coke moving, and this is discouraging. The only answer is that people who usually buy this kind of coal have not bought it thus far and will not because they have oil burners. Local wagonload steam is fairly good and carload is slow. Country demand for steam is nil and country domestic is good in spots only.

### Kentucky Business Is Spotty

Further weakness has appeared in the Kentucky market for prepared coal over the week due to lack of ready demand on account of warm weather and slow buying tactics of consumers and retailers. Steam prices remain unchanged, with both eastern and western Kentucky quoting screenings at 85c.@1 and mine run \$1.50@1.75, some houses asking as high as \$1.85 for mine run. In western Kentucky lump sizes are weaker, block being offered at \$2.75@3; lump, \$2.40@2.75; egg, \$2.25@2.75; nut, \$1.60@2.10. In eastern Kentucky 4-in. block is \$2.75@3.25; lump, \$2.25@2.75; egg, \$1.90@2.25; nut, \$1.60@1.90.

General conditions are good and Kentucky has been getting a good volume of business considering other fields and weather conditions. It also is believed that over winter volume will be greater than in past seasons, due to the fields being favored by low production cost on the non-union basis and ability to absorb freight rates, etc., and get into territory usually served by union mines to the north.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

Index	1924			1923
	Dec. 1	Nov. 24	Nov. 17	Dec. 3
Index	171	170	170	181
Weighted average price	\$2.07	\$2.06	\$2.06	\$2.19

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

Industrial and public utility buying has been sufficient to keep the market well cleaned up in so far as screenings are concerned and at relatively good prices.

West Kentucky has been getting a fair but scattered business. The strike is disintegrating but not enough new tonnage has been produced to affect the market much.

### Northwest Is Still Busy

The rush in coal trade continues at Duluth with anthracite the only laggard. This, however, does not worry the trade, as it is considered that all the hard coal now on hand will move of its own accord before spring. Shipments are good to the docks. Last week 37 cargoes arrived, of which 5 were hard coal, and 16 are reported on the way, of which 3 are hard coal.

Despite the attitude on hard coal sagging prices will not be surprising. There are more than 600,000 tons on three docks, and the total on all docks must be staggering. The supply of Pocahontas goes out as fast as it comes in and purchasers are not buying hard coal when they cannot get Pocahontas but are taking other substitutes such as briquets and other brands of semi-smokeless soft coal.

Docks are working more than full time. Orders in bituminous are coming in and there has been no change in the market. The Dakotas and other Western states are buying.

At the Twin Cities seasonable weather for two weeks has put a snap into the market which has been lacking for many months. There is no wild rush of orders, but a good steady demand, which has made the price schedule steady. There has been no serious congestion of stocks, and now that the winter season is at hand, the market starts with a fairly clean slate.

The first effect of cold weather was to start the retail demand in these cities in a way that has not been felt for a long time. Similarly there was a distinct pickup in the movement of domestic coal to the country. While the effect was to brace the market, it did not result in any changes of price, aside from screenings. These had been dragging sadly because of mild weather. Southern Illinois screenings advanced to \$1.40@1.60; lump coal was firm at \$3.25-@3.50; central Illinois lump was \$2.75@3; western Kentucky lump, \$3. Dock prices remained at their list prices.

There has been no change in the coal situation in Milwaukee aside from a decline in the movement of coal up the lakes as the season of navigation nears the close. There are only a few more cargoes on the way. Dealers report the market quiet, as no biting weather has yet been experienced. The total amount of coal received in Milwaukee up to and including Nov. 26 is 767,394 tons of anthracite and 2,450,155 tons of bituminous coal—3,217,549 tons in all. In the same period of 1923 894,624 tons of anthracite and 3,086,622 tons of bituminous coal was received.

### West Keeps Even Keel

Demand for prepared grades of Kansas coal is so light that, while list prices have not been changed, actual sales of Kansas lump are being made for as low as \$4.50 a ton. The list price is \$5. The screenings market, on the other hand is steadily becoming tighter, with few quotations under \$2.25 and many at \$2.35. Shading also is found in nut, although not so pronounced as in lump. Nut, which for several weeks had stood at \$4, is now being sold at \$3.75@4. There have been no changes in prices in other fields of the Southwestern district, although operating time throughout is averaging not more than 50 per cent of normal.

A slight drop in temperature last week stimulated the Colorado domestic market only a little. However, Colorado mines are doing fairly well, having worked on an average of 31 hours last week, and only 17 per cent of the total working time lost was attributed to "no market." Prices remain unchanged since Oct. 20.

As a result of colder weather, Utah mines are increasing output. Production is now 60 per cent of full-time capacity. Lump coal is not moving as well as it was and intermediate sizes are in better demand. Slack is described as easy. The California market is very good, but demand from the Northwest has fallen off again. The Idaho market is quiet, too, but business is better in Nevada. The home market is fair. The smelting industry continues to be the best industrial customer for coal. Sugar manufacturing in the Salt Lake district for this year is practically over. The shorter run is the result of a light beet crop. The labor situation is good and car supply is practically normal again.

### Weakness Pervades Ohio Markets

The last week has been one of general weakness in the Cincinnati market. Domestic buying was off because of mild weather and the presence of big reserves against immediate buying in most of the retail yards. All movement of lake tonnage had been stopped by the close of navigation. Western fuel shipments were stopped by the fact that a lower freight rate is to be put into effect Dec. 5 and buyers were waiting to take advantage of it. Tidewater call was low because the coastwise business was bad. The byproduct market alone showed any buoyancy. It was much better.

Under all the circumstances prices held up amazingly well. This is explained, however, by a very prompt attempt in the Kentucky and West Virginia districts to check surplus production.

Recent rains have raised the water stage of the Ohio River so that half a dozen big companies engaged in river traffic now are bringing 40,000 or 50,000 tons of coal a week from the West Virginia districts, which is about double the tonnage that had been coming down.

Trade in Columbus and central Ohio continues rather quiet and featureless. As the lower temperatures did not last long, buying is still from hand to mouth and neither steam users nor dealers are inclined to stock up to any extent. Prices on domestic business have weakened as some decline in West Virginia quotations has been noted. It is difficult to find an outlet for demurrage coal. Steam contracting is not brisk and most of those with agreements are taking reduced tonnages. Screenings are selling at low figures because of the closing of the lake trade, which has thrown an additional amount on the market.

Screenings are now providing the only activity which is

discernible in the Cleveland market. These grades continue to be scarce and the prices are rising. There is practically no change in other grades; steam demand is quiet, and the retail yards are pretty well stocked for the winter. No changes in prices are noted on other grades. With the lake season over quite a few eastern Ohio mines are likely to close, causing prices on all grades to stiffen.

### Pittsburgh Market Flops Again

Another slump has hit the Pittsburgh market, it being extremely difficult to sell coal on the open market. Some operators are believed to be inducing customers to take coal by making slight price concessions, the actual prices made not being ascertained. Consumers having regular mine connections are taking coal as usual. The railroads are running as heavily as ever and so are the industries. Domestic distribution, however, has been poor. There is no change in quotable prices save for a stiffening in slack.

The Buffalo market is dubious with so little seasonable weather. The trade has about given up all idea of an active business this winter. Canada is still pretty hard to do business with, as industry in general is dull there and does not promise to pick up much right away. With the nearing of the end of the lake season the supply of slack is short and the demand is better.

There is practically no change in the Toronto market, demand continuing to be light. Quotations are as follows: Pennsylvania smokeless, \$5.85; slack, \$5.

### Dullness Lingers in New England

In New England the steam coal market continues dull and with no prospect of change during December. Shipments are being made in fair volume coastwise, but practically all is being applied on contracts. Spot business is very light, and while efforts are being made to encourage buying against the winter months the consumer is still making only sparing purchases.

At Hampton Roads the accumulations are by no means heavy, but the agencies find themselves obliged to watch the trade closely in order to move current output. Recent sales of Pocahontas and New River of Navy acceptable grade have averaged \$4.20@ \$4.35, with less desirable coals selling off to \$4.

For delivery inland from Boston, Providence and Portland high grade smokeless coals are in ample supply, with only moderate inquiry. At Boston \$5.35 per gross ton is the utmost that these grades command on cars for mine run. Slack is being offered much lower than the usual differential at the mines would indicate.

All-rail from central Pennsylvania there is only a fair tonnage moving into this territory. The selling radius of Southern coals is now wide enough from rehandling wharves here to restrict the opening for rail coal much more than was the case early in the season.

### Atlantic Markets Develop Softness

A softer market for spot coal prevailed at New York last week and it is expected that buying now will be subject to weather conditions. Most consumers have bought quietly and at present are well stocked up. Demand for some grades of West Virginia coal has eased off to such an extent that mining has been curtailed somewhat. So much coal is coming to the New York tidewater piers that it is moved only by intensive sales effort.

At Philadelphia the cold spell quickly spent itself and had little effect on the coal trade. Many large users still purchase a fair amount of spot coal but the amount they buy

under contract has increased recently. Demand is centered on high class coals, which tends to keep the low grade fuels pretty well off the market. Not much coal is standing at tide, as the loadings are very light, with bunkering slow.

Demand at Baltimore is about what it has been for several weeks past, and shipments have more than kept pace with the call for coals for immediate use and storage against the near future. Prices are constant and there has been little change for several weeks past. November exports of coal at Baltimore have continued to lag behind those of October, only two shipments having been made between the 10th and 28th.

Some fairly seasonable weather at Birmingham brought temporary activity in the retail domestic movement, but as yet the mines are booking only scattering orders for small lots. Some mines are well fixed on domestic business under contracts and are booking enough spot orders to move the output, but as a whole the market is sluggish. Buying of steam coal has not materially improved. Bunker demand is reported normal as compared with recent weeks. Quotations are holding fairly steady.

### Anthracite Trade Turns Soft

New York anthracite consumers are taking things easy, most of them having put in enough coal to tide them over a few days of cold weather. Receipts have been cut down by frequent strikes at the mines but independent prices have not been affected to any material degree. Demand for stove coal continues in excess of the supply. Egg and chestnut move steadily, but pea, outside of the best grades, is hard to move. There is some activity in steam coal, buckwheat being in a little better demand, with rice and barley a trifle easier than last week.

The little splurge at Philadelphia occasioned by the brief cold spell soon disappeared and dullness has overtaken the retail men. The operator has not felt the dropping off in retail demand, as the dealer is trying his best to store away all the coal that is due him. Nut is in heavier demand and is extremely short with some shippers. There is a strong call for stove, but the gap between this and nut widens almost daily. All shippers continue to have some difficulty in moving egg and pea is almost as bad. Steam coals are quiet and the demand is fairly well met.

Continuance of mild weather at Baltimore has limited hard coal burning to a moderate amount. Supplies in yards are ample to meet all demands and there seems to be no scarcity of any particular size at present. The trade is much interested in just how much attention will be attracted by the coming exhibit in this city of burning devices for buckwheat size coal.

Soft weather at Buffalo is making it hard to sell anthracite. Consumers prefer to use gas, even if it costs more, as it gives so little trouble. Consumers seem indifferent of the future and refuse to buy coal when the weather is mild. They are looking for cheaper substitutes and they seem to find them.

Toronto dealers are quite busy, the setting in of cold weather having stimulated the domestic demand.

## Foreign Market And Export News

### Lean Foreign Trade in British Market; Slight Upturn in Output

Some improvement in the Welsh coal trade is evident due to the arrival of tonnage delayed by the recent heavy weather. Inquiries are more numerous but demand must show a much greater increase before business can be said to be anywhere near normal. Most of the collieries have enormous stocks of coal still standing, and it is the exception to find a pit working more than three shifts per week. Several pits have reopened this week but the relief to the heavy unemployment in the Welsh fields has been counteracted by the closing down of more pits. France is buying slightly more coal and there are more inquiries from South America. Italian business is very slow. Much foreign business is going to Germany and America.

The official audit of South Wales trade shows a net loss every month since the May wage agreement, the total loss for the first four months being £629,843. The October audit probably will increase this loss. Colliery owners are losing heavily on the present price basis and many contracts expiring at the end of the year will not be renewed. The future depends upon resumed production of European manufactures or on lower wage cost through an eight-hour day. It is stated that the miners' leaders are organizing for a reduction of working hours to effect the absorption of unemployed and also for an increase in the minimum wage from 8s. 3d. to 12s. per day.

The Newcastle market shows an all round slight improvement, but steams have made more headway than the other classes. Gas coal is in fair demand on the Continent. The situation here changed from an oversupplied and vacillating market to distinctly hardened prices. The Genoa gas works are asking for 30,000 tons of Durham gas coals for shipment from January to May, 1925, and Gothenburg for 10,000 tons of Wear gas coals for shipment from January to March, 1925.

Production by British collieries in the week ended Nov. 15, a cable to *Coal Age* states, totaled 5,232,000 tons, according to the official reports. This compares with an output of 5,137,000 tons in the week ended Nov. 8.

#### Prices Soften in Dull Market At Hampton Roads

The coal market at Hampton Roads is dull and prices are soft, with inquiries slackening and bunkers and coastwise alone holding their own. Foreign business is decidedly spotty and showing a tendency to decrease.

Supplies at the piers have been increasing and an increase in coastwise movement was reported. Piers have arranged to operate on Sundays in order to accommodate ships more readily, and this action has had a tendency to increase future business. As a whole the market is dragging.

Softening of prices is attributed to increased supplies at tide. Retail business is booming but has had no effect on the market as the winter's supply have already been provided for at contract figures.

#### Lower Output Not Likely to Affect French Market

With 23 working days in November—Nov. 1 and 11 are holidays in France—output is expected to be lower, but on the whole the situation is unchanged. There has been a slight increase in inquiry for industrial coals, due to heavier consumption in the plants and further pressure of sterling, which increases the cost of British coals.

Activity is relatively moderate in house coals and bituminous screened fuels are selling freely.

Deliveries of indemnity fuels to France and Luxemburg in October amounted to 516,700 tons of coal, 328,800 tons of coke and 39,300 tons of lignite briquets, a total of 884,800 tons.

In the first six days of November the total receipts were 64,300 tons, including 51,300 tons of coal; 3,900 tons of coke and 9,100 tons of lignite briquets. Deliveries were resumed on a normal scale Nov. 10.

Under the Reparation Commission's plan, the share of France in the apportionment of indemnity fuels between the Allies as from Nov. 1 will be 671,000 tons a month (250,000 tons of coke), but with the meager deliveries during the last fortnight it is doubtful that the Germans will be able to meet their commitments this month.

## News Items From Field and Trade

### ALABAMA

The construction of two washers, one costing \$50,000 at Dora, and the other costing \$20,000 at Jagger, was announced by the Pratt Fuel Corporation. Operations will begin during December. The washers are of small types but are expected to care for the tonnages at these two mines. The company is engaged in other construction involving the appropriation of a large sum.

A report to the effect that the Woodward Iron Co. would add a number of Koppers ovens to its byproduct plant at Woodward has been officially denied.

Work is progressing rapidly on the new coal washery and alterations in the tippie at the Empire Mines of the DeBardeleben Coal Corporation, with completion of the improvements planned by Jan. 1. A Montgomery washer is being built and Deister concentrator tables are being installed for treatment of product from  $\frac{1}{4}$  in. down, which it is stated will reduce the ash content of the fines to a very low percentage. About \$100,000 is being spent on these betterments.

Forest fires burning near the Gamble mine, in Walker County, were communicated to the interior of the mine through the airshaft and ignited the coal, which is reported to be still burning. Scarcity of water has retarded the fight to extinguish the fire in the workings, and considerable damage is said to have been wrought at this writing. The mine is a small one operated by L. T. Bouchelle. No men were trapped in the workings as at first reported.

### COLORADO

R. K. Graham has resigned his position as superintendent of the Dick Coal Co. at Boncarbo. He is succeeded by Peter J. Miller. Mr. Graham has moved to California.

Effective Dec. 1, J. B. Marks was appointed assistant to the president of the Colorado Fuel & Iron Co. He also will continue to act as purchasing agent.

### ILLINOIS

Mine No. 1 of the Spring Valley Coal Co., Spring Valley, has resumed work at pick mining. About twenty-seven places have been opened and employment given to seventy men.

Theo. C. Keller, president of the Keller Coal Co., of Chicago, which operates big mines at Hillsboro, Taylor

Springs, Nokomis and Witt, has just been granted a fifty year franchise by the City of Witt to light the city. Keller is negotiating a similar contract at Wenonah, where one of the largest mines is located. He announces that a huge power plant will be erected at Witt to furnish power to run all the company's mines in addition to furnishing the city lighting.

The Spring Creek coal mine, located three and one-half miles northeast of Springfield, was scheduled to begin work Dec. 1, employing 400 men. The daily hoist will be 2,200 tons.

The Wall Coal Mining Co. of St. Louis, capital \$10,000, has leased the old Keystone Mine near Marion. The Cameron Coal Co. has operated this mine since 1917 with Frank W. Coal as superintendent and W. C. Coal, manager. Their plans for the future are not definite. H. W. Bradbury is the new superintendent and H. R. Wall, of St. Louis, is president.

The Cosgrove-Meehan Coal Co., which operates twelve mines in Pennsylvania and five in this state, has purchased the Panama mine on the Nickel Plate railroad, near Panama. This announcement was made by Enoch Carver, Jr., president of Cosgrove & Co., Inc., who are the selling agents for the Cosgrove-Meehan Coal Co. The Panama mine has a daily capacity of 3,300 tons and this will be increased to 4,000 tons. This company will now have the only two mines on the Clover Leaf division of the Nickel Plate.

Pen and pencil nightly replace the pick and shovel of coal-digger pupils enrolled in the educational department of Subdistrict 5, United Mine Workers, which has its headquarters at Taylor, Ill. Organized last convention time on recommendation of President William Daech, the department has proved its success by turning out more than 200 miners as graduates of the first course. Most of the work is done by the miners in their own homes, but they come together in seven different localities—Taylorville, Hillsboro, Panama, Nokomis, Pana, Kincaid and Tovey—twice a month, studying American history, economics and similar subjects.

William Van Dusene, Jonesboro, and associates plan extensive strip mine operations along the old right of way of the M. & O. R.R., near Millstadt. The company plans to purchase 1,000 acres between Millstadt and Smithton, mostly in the High Prairie neighborhood. Options have been taken upon 500 acres at a reported average of \$135 an acre. Drillholes will be sunk at once over this territory. In the High

Prairie region are many small mines, operated mostly by farmers. At one time there was enough extensive mining in this territory so that a narrow gage railroad, privately owned, was operated to Millstadt, where there was a tippie and standard gage railroad loading plant.

Production in the Shuler mine, at Alpha, on a recent day totaled 622 tons, which is a new high record for single day production at this new shaft. Approximately 100 men are employed. The mechanical equipment at Alpha provides for eventual output of 2,000 tons.

Announcement has been made that the Radium mine, owned by the Aluminum Ore Co., in the Belleville field, will be closed down indefinitely, possibly for the entire year. The company finds purchasing of coal upon the open market cheaper than operating the mine. More than three hundred men have been thrown out of employment.

### INDIANA

The West Jackson Hill Coal Mining Co. at Sullivan, has filed a preliminary certificate of dissolution.

A committee of operators of strip mines in southwestern Indiana headed by Roy E. Price, of the Stockton Coal Co., has proposed to Richard Lieber, director of conservation of the state, that the operators of these mines turn the land over to the state for game preserves. The committee proposes to give the lands to the state with the provision that the department reclaim them with native vegetation. The conservation officials are considering the offer.

With about eleven mines working daily in the Clinton field, a marked improvement in the mining industry is noticeable in that section. Not long ago not more than five mines were working. According to operators from that section, there likely is to be a gradual betterment in the industry.

A verdict of \$25,000 damages was given Nov. 21 in federal court in Indianapolis to James Gatherun, former mine boss of the Queen Coal & Mining Co. at Jasonville. Gatherun, who had been mobbed and chased out of town, brought suit against thirty-three residents, asking \$50,000, but charges against two of the thirty-three were dismissed. The case attracted statewide attention, since for a time Jasonville developed symptoms of becoming another Herrin. Among the defendants, who failed to give any support to the mine boss when miners concluded he no

longer was wanted, were the Mayor, Chief of Police, one patrolman and the financial secretary of the local of the United Mine Workers.

## IOWA

Drilling for coal at Bedford will begin at once. Three holes will be drilled at first, the expense to be covered by public subscription. Coal was discovered at Bedford in 1879, and there are a number of places in the vicinity where prospecting can be done. Since the establishment of a mine at Gravity, interest in the project has steadily grown.

## KANSAS

A movement to force a special convention of the United Mine Workers of District 14 to consider the removal of the present district officials and to place the name of Alexander Howat on the ballot at the biennial election in December was launched at a mass meeting of 2,000 miners in Arma, Nov. 16. The action was precipitated by the board refusing to place the names of Howat and more than a score of other candidates on the ballot on the ground that the international had ruled them ineligible. At the mass meeting copies of a form of resolution, the adoption of which by twenty locals would require the calling of a convention for not later than Dec. 4, were distributed.

## KENTUCKY

The Pontiac Mining Corporation has acquired the property of the Pontiac Coal Co., Madisonville, including coal mines, houses and other equipment.

The Swift Coal Co. will develop coal land in the neighborhood of Roxana, and will not only establish a plant but develop a mining town.

C. W. Johnson, attorney, has been named receiver for the Dixie Diamond Coal Co., retailers, 1201 East Main Street, Louisville, by Judge George A. Brent, referee in bankruptcy. Petition for receivership was asked by Harry J. Hood, president of the company, and John B. Carroll, receiver for the Looney

Creek Coal Co. Receiver Johnson was instructed to report on the advisability of continuing the operation of the company, as requested by Mr. Hood in the petition.

T. P. Middleton, Assistant Banking Commissioner, in charge of the Blue Sky Department, has granted permission to the Montgomery Creek Coal Co., of Vilco, to sell \$85,000 in bonds for the payment of company debts, the bonds to carry 6 per cent and to be issued to each creditor in amount not exceeding the sum due that creditor from the coal company.

It was stated at Harlan on Nov. 17 that the Wisconsin Steel Co., operating at Benham had increased its production to thirty-five cars a day and was operating six days a week since the election.

## MINNESOTA

The Clarkson Coal & Dock Co. has sold an issue of 6 per cent gold bonds in the sum of \$6,500,000. The money is to be used for refunding and for improvements. The bonds were snapped up as soon as offered which is considered a good sign by coal men of the Northwest.

## OHIO

The date for the sale of the assets of the Maynard Coal Co., of Columbus, which went into the hands of receivers William S. Harman and Frank L. Stein, about a year ago, has not been set but it is expected it will be offered for sale under order of court some time in December. The assets consist of working mines in the Pomeroy field in Ohio and the Hazard field in Kentucky. There are four large mines in Ohio and three in Kentucky. The Kentucky mines have been operated by the receivers and have been showing a good profit, but the Ohio mines are closed.

The LaBelle mine, at Steubenville, owned by the Wheeling Steel Co., of Wheeling, W. Va., was the scene of a recent explosion while 125 men were at work. All escaped without injury except one man who was seriously burned. The LaBelle mine is adjacent to the Brentwood mine, which claimed 119 lives in an explosion in April.

Jerome Watson, chief of the state mine division, recently learned also that miners had become ill from fumes and gases while working in the Blue Rock mine, owned by the Blue Rock Mining Co., of Zanesville, 17 miles east of that city. This mine had been sealed since the flood in 1913 and was opened in October, 1924. Inspectors were unable to locate the source of the gas. It is thought that the mine will be permanently sealed.

Quite a few coal men of Columbus attended a meeting of the Ohio Valley Shippers Advisory Board, which was held at Louisville Ky., recently. Included in the number were G. K. Mitchell, traffic manager of the New York Coal Co.; H. S. Morris, traffic manager of the Hocking Valley R.R., and others. William E. Tytus, sales manager of the Sunday Creek Coal Co., was named vice-chairman of the coal and coke committee of the board.

## OKLAHOMA

Ernest Ingram, assistant sales manager of the McAlester Fuel Co. for the past six years, has resigned and accepted the position of sales manager of the Gem Coal Co. of Henryetta.

## PENNSYLVANIA

A plot of ground at Larksville, near Wilkes-Barre, one-fourth of a mile square, dropped from 5 to 10 ft. early Nov. 26 as a result of a mine disturbance in the operations of the Hudson Coal Co. Five properties owned by the company were in the affected area, two of which were damaged beyond repair. Although the families in the sunken area and in the adjoining sections were thrown from their beds, there were no casualties.

The Pennsylvania Coal & Coke Co. and subsidiaries report an October deficit of \$40,359 before federal taxes, but after depreciation and depletion, against a deficit of \$10,431 in October, 1923. The deficit for the first ten months of 1924 totaled \$329,015, against a surplus of \$726,221 in the corresponding period of 1923.

The coal and coke business in the vicinity of the Connellsville coke region is still on the increase, although prices are remaining about stationary. The Century Coke Co., at Brownsville, with 205 beehive ovens, is preparing to resume operations next week, as is also Pike mine of the Hillman Coal & Coke Co., a union mine on the edge of the coke region at Brownsville.

Fire recently destroyed the breaker, blacksmith shop, wash shanty and air compressor room of the Wilson Hill Coal Co. at Simpson, causing a loss of \$30,000. Firemen prevented the flames from reaching a building in which powder was stored.

Directors of the Lehigh Valley Coal Co. held their monthly meeting last week, but did not announce a dividend. Since the separation of the coal and railroad interests, at which time much stock changed hands, stockholders have been waiting for a dividend to be

A Few Shovelfuls for a Chilly Day

This snapshot, taken late in October, shows a pile of domestic sizes of anthracite at the storage plant of the Hudson Coal Co., near Jermyon, Pa. The coal was mined during the last summer.

declared. Several meetings have been held without any action being taken. Efforts to elicit any further statement from the officials of the company other than that there had been no declaration of a dividend were unavailing.

## TENNESSEE

Leonard C. Crewe has resigned as president of the LaFollette Coal & Iron Co. and the Volunteer Fuel & Iron Co., both of LaFollette. Until Mr. Crewe's successor has been elected, S. S. Pratt, of LaFollette, vice-president of the company, is acting as president.

## UTAH

J. R. Roaf, engineer at the Kenilworth mine of the Independent Coal & Coke Co., left Dec. 1 to become superintendent of the Royal Coal Co. at Rolapp. Mr. Roaf has had considerable experience in the Crows Nest Pass country, in the Yellow Head Pass and Vancouver Island Coal fields in Canada.

Moroni Heiner, vice-president and general manager of the United States Fuel Co., of Salt Lake City, for several years past, has resigned the general managership and will be succeeded by D. D. Muir, of the United States Smelting, Refining & Mining Co., which has offices in the same building as the coal company. Mr. Heiner was one of the organizers of the company and holds a large block of stock in it. It was stated that he will retain his office of vice-president and still take an active interest in the company. He probably will take a rest on the Pacific Coast for two or three months.

## VIRGINIA

A dividend of 2½ per cent has been declared on the preferred stock of the company by the directors of the Virginia Iron, Coal & Coke Co. payable Jan. 2 to stockholders of record on Dec. 13.

## WEST VIRGINIA

The Shriver Coal Co. settlement on Scott's Run, an open-shop operation, was the scene of disorders Nov. 26 during which a child was seriously wounded and an attempt made to dynamite the tippie. Two explosions ripped out a part of the approach to the tippie and damaged the loading apparatus. The blasts were followed immediately by rifle shots from a hillside. Sarah Rokys, five years old, standing in the doorway of the cabin occupied by her parents, suffered a wound in the chest. Attending physicians said she could not live.

Following closely on the heels of the election, the Pulaski Iron Co. ordered the immediate firing of its entire battery of 600 coke ovens at Eckman. It is stated that active preparations are now being made to assemble the necessary working forces to put the ovens in blast.

Late in November a large number of new coal cars for the Pinnacle and Crane Creek operations of the American Coal Co. were received. The plants of the company are working regularly

and are loading more coal at present than at any time during the year.

Figures compiled by the Chesapeake & Ohio show that there were 43,339 cars of coal loaded on that road in November, up to and including the 18th, with every prospect that the heavy loading of October will be equalled in November. Loadings by fields during the first eighteen days of November were as follows: New River, 10,186 cars; Kanawha, 6,336; Coal River, 3,512; Logan, 18,481; Kentucky, 4,823.

W. A. Richards, of Pottsville, Pa. has been made general manager of the Pemberton Coal & Coke Co., in the Winding Gulf district; the Ashland Coal & Coke Co., in the Pocahontas district, and the Majestic Collieries Co., operating on the Kentucky side of Tug River in the Thacker district. The total output of the mines of the companies mentioned will average over a million and a half tons per year. The new general manager is the son of W. J. Richards, president of the Philadelphia & Reading Coal & Iron Corporation, and has been identified with the coal industry since he was a young man. He is a graduate of Lehigh University. Mr. Richards will have his headquarters for the present at Ashland.

Since the early part of November the Nuriya Smokeless Coal Co., operating at Nuriya, nineteen miles west of Mullens, of which W. H. Ribt is general manager, has been running its mines regularly and giving its men daily employment.

Deputy sheriffs and state police have been investigating an explosion that wrecked the aerial tram coal conveyor of the Clarksburg Big Vein Coal Co.'s mine west of Adamston a few days ago. The mine was out of commission for several days as a result of the explosion, which entailed damage to the extent of about \$2,000, according to officials of the company. The company has been operating on a non-union basis since April 1 last. The explosion was the second one at the same mine within four months. Another explosion occurred not long ago at the Fort Pitt mine at Wilsonburg, the owners of which are affiliated with the owners of the Big Vein mine.

## WYOMING

By Dec. 1 the sixteen mines of the Union Pacific Coal Co. in Wyoming were all equipped with Edison permissible cap lamps. The electric cap lamp has been used at the Cumberland and Hanna mines of the company for several years, but it is only within the past two weeks that they have been adopted in the Rock Springs area.

The Rock Springs chapter of the Rocky Mountain Coal Mining Institute held its November meeting at Reliance, Nov. 20. This chapter has adopted a program for the winter which will cover the study of mining conditions in southwestern Wyoming, members giving reports on the different problems at each monthly meeting. As the membership is scattered through the several camps around Rock Springs, a meeting will be held at each place. Miners in-

terested in problems of the industry are being encouraged to join this chapter.

The Water system being constructed by the Union Pacific Coal Co. at Reliance is nearing completion and the company has its geologist conducting a survey of the Superior vicinity in search of a better water supply for that camp.

Jack Smith, safety engineer for the Union Pacific Coal Co., returned Nov. 21 from a trip to Trinidad, Colo., and Raton, N. M., where he was studying the rock-dusting methods used in those fields.

## CANADA

The railroads are finding that they need only about 75 per cent of the steam coal they had stored for consumption, as the grain crop is much smaller than was expected. The result is that the steam coal mines in the West are obliged to shut down, as was the case at Fernie and Coal Creek. The Drumheller mines are all working on orders for the prairies, mostly for Manitoba and Central and Northern Saskatchewan.

The One Big Union is having difficulty in functioning in Springhill. Ben Legere, organizer, from Lowell, was not allowed to speak indoors on the ground that permission of the local officials of the United Mine Workers must first be obtained. Legere failed to obtain this consent and was forced to address his followers and others from the front of the hotel in which he was, a guest. About 65 per cent of the Springhill local has decided to remain within the miners' union and will not affiliate with the Communist or the One Big Union factions.

## New Companies

The Daisy Coal Co., Krypton, Ky., capital \$10,000, has been chartered by William Stott, Daisy Stott and Edgar Harris.

The Miners' Co-Operative Coal Co. has been chartered with an authorized capital of \$15,000 to mine coal in the Bergholtz (Ohio) field. The incorporators are: J. C. Stabley, Steven C. Tolick, J. P. Kinney, Patrick Harvey and J. E. Guy. This is one of the many co-operative mines being opened in Ohio.

A new coal company launched in West Virginia about the middle of November was the Inspiration Mining Co., with headquarters at Clarksburg. The company has a capital of \$25,000. C. D. Floyd and associates organized it.

The Coaton Colliery Co., P. O. Building, Wellston, Ohio, has been chartered with an authorized capital of \$25,000 to mine and deal in coal. Incorporators are W. H. Parker, Grant McGhee, George Shook, H. R. Kisor, A. M. Scott and L. E. Vogelsong.

Papers have been filed chartering the Liberty Coal Mining Co., of Columbus, Ohio, with an authorized capital of \$10,000, to mine, buy, sell and deal in coal. Headquarters have as yet not been established but they will as soon as suitable location is found. A mine is being operated at Moxahala, Ohio, in the Syndicate field, on the T. & O. C. R.R., mining Hocking No. 6 coal. Chas. A. Brunner, Albertus M. Steck, W. W. Daniel, Harold J. Roberts and Edward S. Beard, all familiar with coal operations, are the incorporators. Officers as yet have not been elected.

Papers have been filed incorporating the Bituminous Collieries Co., Cleveland, Ohio, with a capital of 3,750 shares, no par value designated, to mine coal and deal in coal and coke. Incorporators are Frank T. Kerr, William R. Butcher, Jr., Lawrence E. Imhoff, Winifred A. Gray and John C. Nichols.

## Traffic

### Seek Freight Rate to Throttle Non-Union Mines

Harlan (Ky.) operators have been advised that an effort is being made to bring pressure to bear on the Interstate Commerce Commission to impose a freight rate differential of 75c. a ton on coal going into the Northwest from the Harlan district, as compared with coal moving from the Central Competitive or union fields. It is claimed that Central operators as well as union labor would like to throttle the non-union Kentucky sections.

It was reported from Harlan on Nov. 22 that the Louisville & Nashville R.R., with an average of 1,067 cars of coal daily off the Cumberland Valley Division had set a new week's loading record for the division. It is also stated that there will be some double tracking of the division next year, due to great increase in tonnage handled.

### Sustains Reduced Coal Rate To East St. Louis

Judge Crow, at Belleville, Ill., has sustained an order of the Illinois Commerce Commission ordering a 21c. reduction in coal rates to East St. Louis from mines within a radius of 20 miles of East St. Louis. He ruled against the 30-mile radius. The new rate is to be 71c. on coal within the 20-mile circle and 91c. on coal beyond in what is now the 91c. rate field. The important Mt. Olive and Staunton fields are outside, as well as the Sparta, Marissa and Coulterville groups. Coal moving out of Illinois will not be benefited—the rate is local to East St. Louis only. It is likely that the railroads and important operators in the territory discriminated against will further contest this order.

### Rates Shaded in South Dakota

The South Dakota Railroad Commission announces some concessions in freight rates on coal to various points in that state, principally the western part. Reduced rates have been arranged from the docks on Lake Superior and Lake Michigan to territory west of Chamberlain and Pierre, on the Missouri River. Another reduction is expected to points on the Pollock branch line of the Soo and also on the Fairmount (N. D.) line which extends into South Dakota. Reductions have been made from the Illinois mines to western parts of South Dakota.

## Trade Literature

**W. A. Jones Foundry & Machine Co.**, Chicago, Ill., in its catalog No. 29, on gears, covers the subject quite extensively. It contains 224 pp.

**Illinois Chain Grate Stokers**, Illinois Stoker Co., Alton, Ill. Third edition of Catalog L. Pp. 62; 8 x 11 in.; illustrated. Embodies a complete discussion of type A (natural draft) and type G (forced draft) stokers. A number of blueprint drawings are included, and the catalog should prove valuable to power-plant operators.

**Tipple Equipment**, Fairmont Mining Machinery Co., Fairmont, W. Va. Pp. 32;

8 x 11 in.; illustrated. Describes the different installations made throughout this country by this company. The book is well illustrated.

**Herman H. Sticht & Co.**, 15 Park Row, N. Y., manufacturers of electrical and industrial instruments, have just announced the publication of a new bulletin No. 123 on the subject of **what constitutes safe insulation**. This little bulletin explains in a concise manner how and why electrical insulation breaks down. It also points out the value of periodically testing all electrical equipment.

## Industrial Notes

**The John F. Folkers Engineering Corp.**, Mobile Ala., has been appointed agent to handle sales and service for the **Triumph Electric Co.**, of Cincinnati, in the Mobile territory.

**The Hitchman Coal Co.** is having a new conveyor system installed at its mine at Moundsville, W. Va., by the **Fairmont Mining Machinery Co.** The conveyor is to be somewhat similar to those used at Lorain and will be utilized in coaling all Baltimore & Ohio engines at the western end of the Wheeling division as well as to load coal in cars for shipment. This conveyor will reach a short distance into the shaft of the mine, where a new type of coal car especially designed for conveyor work will bring the coal from the various sections of the mine to the conveyor pit, from which point the coal will be carried to the top of the tippie ready to be shipped out. As soon as the new conveyor system is completed the large coal tippie, extending the full distance from the mine over the B. & O. yards and out over the storeroom department of the local railroad will be torn down, although only recently reinforced by cement foundations and cement holdings along the side girders.

**W. F. Hebard & Co.**, 551 W. Van Buren St., Chicago, Ill., has been appointed to act as sales representative of the **Ironton Engine Co.**, in the Chicago district, particularly in connection with Ironton storage battery industrial locomotives.

## Association Activities

At a general field meeting of the **Winding Gulf Operators Association** held in Beckley, W. Va., late in November, the association passed a resolution opposing the proposed child labor amendment to the federal constitution. The association also expressed appreciation of the assistance of Col. W. J. McClaren of McDowell County in giving impetus to road building in West Virginia. Colonel McClaren has resigned as road engineer of McDowell County.

## Obituary

News was received at Lexington, Ky., on Nov. 25, of the death in a hunting accident at Umatilla, Fla., of **J. W. Reedy**, 50, formerly a prominent coal operator of Lexington, Ky. He was formerly associated with C. R. Luttrell, of the Montgomery Creek Coal Co., at Vico, in Perry County, Ky.

**Thomas Worth Currie**, age 36, who had been connected with the New Castle Coal Co. for a number of years and was well known in coal circles, died Nov. 22 after a short illness with pneumonia. Mr. Currie is survived by a wife, two children and several brothers and sisters.

## Coming Meetings

**West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers**. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

**American Institute of Mining and Metallurgical Engineers**. Annual meeting, Feb. 16-19, 1925, 29 West 39th St., New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers**. Midwinter convention, Feb. 9-13, 1925, 29 West 39th St., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Ends Disputes About Powder

One source of friction, difficulty and misunderstanding between miner and management at many coal operations is the alleged faulty issuance of powder or other explosive. In the past this in many cases has constituted the root of much unpleasantness, sometimes bordering upon hostility.

In order to forestall all possibility for misunderstanding in this regard **Frank Zgol of Sandoval, Ill.**, has in-

### TriPLICATE Check and Check Book

One stub is given to the magazine keeper as an order for powder, one is hung on the outside of the miner's tool box to be taken up by the powder-car driver as a receipt and one is retained by the miner. All stubs bear the miner's check number.

vented and patented the system of triplicate checks shown in the accompanying illustration. As may be seen one of the check stubs carries a calendar on which the date when powder is ordered or delivered may be marked. This stub is retained by the miner.

One stub is given to the powder-house keeper and constitutes the order for powder. The third stub is attached to the miner's tool box and is collected by the man who delivers the explosive. It becomes the company's receipt. The driver of the explosives' car will not deliver powder to any tool box unless such a receipt stub is hung on the outside of the box. These triplicate checks can be made up in book form for convenience.

### Build Electric Locomotives on Lines of Steam Units

It has often been said that the coal industry in the solution of its great transportation problem might advisedly emulate the example of the railroads in the design of its rolling stock. This unquestionably is in large measure true, for railroad construction today is the outcome of many years of experience. Although the problem of railroad transportation differs radically from that of mine haulage, requiring in many respects a different type of construction, yet their many points of similarity render the adoption of certain details of construction highly advantageous.

With some such idea as this in mind, when the Vulcan Iron Works, of Wilkes-Barre, Pa., some months ago set about designing a line of electric locomotives, it drew liberally upon the experience

gained in its many years of steam-locomotive building. Among the important constructional details that in a measure have been borrowed or adapted from the design of steam locomotives are the bar frames and the three-point suspension of the entire chassis. The brake rigging employed also has been adopted in a large degree from steam practice.

Taking up these constructional features in greater detail, the bar frame is simple in design, easily constructed and amply strong. In these machines each side frame is cast in one piece of steel. While abundantly rigid, such frames permit practically a free circulation of air, thus affording adequate ventilation to the motors and other parts. Furthermore all parts of the machines within the frames may be readily seen and inspected through the openings in these members.

#### RIDING AND TRACKING EASY

In the past many attempts have been made to equalize the weight carried by the several drivers, but only a mediocre degree of success has been attained. In these locomotives the same principles of design have been followed and as far as possible the same construction has been adopted as has proved so successful in the building of steam machines. The springs are built of semi-elliptic leaves. On the trolley type of locomotive one set of springs supports the frame directly through hangers. One end of the other pair of springs is held by hangers, the opposite ends engaging an equalizing bar extending across the machine supported in the center.

By this means the locomotive is enabled to follow without difficulty any ordinary inequalities in the track. In the storage-battery type of locomotive a similar result is accomplished by connecting the inner ends of the springs by means of a system of equalizing levers, links and bell cranks.

In the trolley type these locomotives are built regularly in 4-, 6-, 8-, 10-, 12- and 15-ton sizes. The storage-battery machines are built regularly in 6-, 8- and 10-ton sizes, the battery making up about one-half this total weight. Any standard battery may be used, either of the lead-acid or nickel-alkali types. Removable battery boxes (so arranged that one battery may be lifted bodily

#### Trolley-Type Locomotive

This machine has the type of suspension that has proved successful on steam locomotives. The brake rig has also been adapted from steam practice as well as the frames and springs. Bumpers and drawheads may be made of any type to suit the cars to be handled.

from the machine and charged while the locomotive is operating from another battery) are sometimes used.

Usually steel-tired iron-center wheels are used on these locomotives. However, rolled steel wheels or cast-iron wheels with chilled treads may be applied. Bumpers and drawheads may be made of any desired size, shape or height to suit the cars to be hauled. The trolley type of machine is fitted with the ordinary wheel-crank brake. The storage-battery type on the other hand is supplied with a quick-acting, self-locking brake consisting of a lever actuating a cam. Throwing this lever through half a circle applies or releases the brake which is self-locking both in the on- and off-positions.

Either type of these locomotives may be built to any track gage from 30 in. to standard (4 ft. 8½ in.). The wheel base may likewise be varied within reasonable limits, as may also the height.

#### SINGLE-MOTOR BATTERY LOCOMOTIVE

In the storage-battery locomotive only one motor is used, this being mounted at the forward end of the locomotive just in rear of the bumper. By means of a segmented shaft, flexible couplings and worm-gearing, motion is transmitted from this motor to the driver axles, thus utilizing a type of drive the utility of which has been proved in motor vehicles, automobiles, cars, trucks and tractors.

The side frames are planed upon one side and along the upper edge, the dis-

tance pieces spanning the journal openings are mortised into the frames as well as being bolted into place, and the bolts holding these distance pieces in position are not only lock-nutted but are provided with projecting ends so that even when they are upset in hammering out a bolt the thread itself is not injured.

#### Disconnecting Switch Well Insulated and Protected

An inclosed primary disconnecting switch for use in vaults ahead of the oil circuit breakers on circuits of 4,400 volts and under in capacities from 100 amp. to 400 amp. has been placed on the market by the Line Material Co. of Milwaukee. The box is made of seasoned wood, painted inside and out with two coats of weatherproof paint, has dovetailed joints and is put together with screws. "Transite" barriers are used between switches. The door is hinged on both sides and can be padlocked if desired. A pull stick is mounted on the inside lower end of the door. Brown glazed porcelain bushings at top and bottom of the box provide for the wires, and the flexible contact clips are mounted on wet-process porcelain petticoat insulators which are securely bolted to a channel base, which is in turn bolted to a channel box to channel-wall straps extending each side of the box with holes for attaching to the wall. The box can be closed with the switches open.

#### Storage-Battery Locomotive

One motor, with shaft parallel with the track, is used on this machine. This transmits its power through a segmented shaft and worm gearing to the axles. Pressure on the journals is equalized through a system of levers and bell cranks.

## What Is Safe?

MANY of us are ready to call safe that which can be used safely, but in practice we need a stricter definition and may define a safe device as one that probably or generally will be used with safety. When the life of one or two is involved that will serve as a definition of "safe" but when the lives of hundreds of men are jeopardized as a result of a single indiscretion we begin to take the view that only that which can never be used unsafely is safe. It is in some such sense that Dan Harrington has discussed the flame safety lamp and declared it unsafe. It is in such a way that we can designate the electric safety lamp safe and justify our designation.

Flame safety lamps, like certified explosives, at best can be designated merely permissible, not safe. Safe indeed they may be termed if they are used rightly. Used wrongly they are dangerous. The word "safe" where anything is so only when used rightly is a dangerous word—a bar to safety, a hindrance to progress. We need better flame safety lamps and better explosives and the words permissible or permitted would serve to emphasize that fact.

## Hygroscopic Dusts

WHERE is the cheap non-hygroscopic dust that will remain dry in a damp atmosphere? Alas, we know of but one—coal—and that is so explosive that we wish it were hygroscopic. Perhaps, however, there are others that, placed in a rock-dust barrier, will keep their condition. Nearly all the components of the earth take up moisture and bind themselves into rocks. In the crusher we merely reverse conditions temporarily. Time, which bound the rocks together in the past, soon binds the separated particles together again and laughs at all our efforts.

Nowhere do we need permanence of condition more than in our aircourses where it is so difficult to replace the dust and where frequent ingress and egress through the stoppings makes it difficult to prevent leakage of air. If we must make our stoppings temporary we are almost obliged to have them leaky, thus reducing the efficiency of the air on which safety so greatly depends. Find us then this non-explosive, non-hygroscopic dust, ever ready, no matter how long it has lain, to rise in a cloud when occasion demands.

Crockery, vitrified-brick and marble dusts are perhaps suitable. Shall we come, therefore, to the time when barrier dust and perhaps all dust for rock dusting is first vitrified and then crushed? Shall broken crockery, overburned brickbats, marble-quarry waste, slags and cinders, especially the cinders from the burning of pulverized coal, be our most dependable source of supply? Will these be found harmless to the respiratory organs? And if they are injurious shall we use them only in unused return aircourses or in suspended or shelf barriers where they cannot injure anyone?

## Keep Hoover's Men Abroad

COAL operators, especially those of the Crescent groups with a direct interest in America's coal export trade, might well speak a good word to their Congressmen for the Winslow-Jones bill. This measure, which did not pass at the last session of Congress because it came up too late to get on the calendar without a suspension of rules, would make permanent the foreign service of the Department of Commerce. As it is, the fourteen commercial attachés, forty-two trade commissioners, thirty-five assistant trade commissioners and nineteen American clerks in the department's forty offices scattered through the trade centers of the world never know whether their jobs are to continue until Congress periodically acts upon the departmental budget. If an appropriation sufficiently large is made, they continue; if not, they don't.

Permanency for this foreign service should be provided. Surely it has justified itself during the years that it has been functioning since 1913, and especially since the war. Coal men interested in export trade never before had such an adequate insight into coal market conditions abroad as they have now. Periodic and accurate information laid on their desks regularly and with frequency has taken much of the guesswork out of export. It has brought information that meant business. It has educated a good many coal men who needed educating. This service, which is a small part of the benefit American business reaps, certainly should be continued—with guaranteed permanence.

## Let the Foreman Do It

WE MUST get away from the idea that the foreman must do everything. It is surprising that we did not pass laws to make him test the places for gas before the miner went into the mine. One wonders why we did not require him to set all the props, so eager were we to ask the foreman to assume all the jobs in the mine that carried any degree of responsibility. Much better would it be to prescribe for him a certain number of helpers in a given area of operation and to require them to be capable.

In Great Britain the custom has been, as in Illinois, to put unreasonable restrictions and burdens on the manager. It has only made of the manager an official of lower caliber. The laws regarding the mine foreman are equally unfortunate. When the foreman is required to do more work than is physically possible, he neglects part of it. He does his best perhaps but usually the work required of him by the state goes by default. This is what always happens when we ask the impossible. "Let the foreman do it," is an unsafe cry. "Let him delegate it to a sufficient force of capable men under his supervision and direction," is a counsel of moderation that will end in our getting more closely what we seek.

## White House Wages

SAYS Holy Writ, "Agree with thine adversary quickly whilst thou art in the way with him, lest at any time the adversary deliver thee to the judge and the judge deliver thee to the officer and thou be cast into prison." With some such point of view the union operators signed the Jacksonville agreement. They had tried on several occasions to disagree with their adversary, the United Mine Workers of America, but the public and the administration had always been found to have their faces set against them, and they decided that on this occasion they would agree with their adversary without delay before the irate public ventured to take them by the neck and regulate or nationalize them.

The Jacksonville agreement seemed quite plausible. The price of coal it is true, was not high, not high enough to meet the old wage scale satisfactorily, but if the wage rate was decreased the price would be lowered in an equal degree, for the non-union operator would be well justified in the minds of his own men and in that of the union in reducing wages accordingly. So nothing was to be gained by lowering wages 10 or even 20 per cent. It was hoped that the non-union mines, which had been subject to continued attacks from the union when paying relatively high wages, would hesitate to cut wages drastically and thus invite union activity. In fact the non-union regions were rather doubtful as to the advisability of any such action and did not want to cut wages, but competition among themselves soon brought them to such a pass that they had to cut them more and more until they had pared them to the quick. The non-union men accepted these successive reductions, and the union mines were left high and dry with no market. Even their men, in places, deserted them to get work in non-union regions.

The trouble with the Jacksonville agreement was that it provided for a three-year continuance. It was conditioned on nothing. The union operators cast their future to the winds for three long years. They mortgaged their very existence for a period so long as to jeopardize their stability. Business can hope over a season or a year, but it looks askance at three years of no market.

At an appeal to patriotism and interest in the public weal the operators agreed to the Jacksonville wage scale. Did the public, which requested it, agree to buy of those that paid it? Not at all, not for one instant. They bought where they could get coal cheapest. They imposed the wage but they refuse to pay it. Thus they euchred the union operators. Will the operators feel again the compulsion to sacrifice themselves to the public weal? We think not. They will never again agree with their adversary quickly, regardless of judge and officer.

They have a right to consider their own interests in the matter. It does not concern the operator much what the miner is paid; he would sooner pay a big wage than a small one, but if the public wants to set the wage for certain operators and not for others it should buy from both its accustomed percentage. Conversely, if the public, as indeed it always does, wants to buy open shop, from union or non-union mines alike as is its pleasure and its right, it should set the wages for all alike or set them for none of them. However, the public should not regulate wages in non-union mines; it should recognize the right of mines that are unionized to make their own contracts without public pressure.

## Facing the Inevitable

NO ONE can fail to sympathize with Warren Stone, of the Brotherhood of Locomotive Engineers. He, probably, with a lot of budding capitalists and with some who have been in business many times already doubtless, believed that he could be a new type of industrialist who would pay high wages, give his men the best of working conditions and be hailed as a benefactor of mankind. Many working men and salaried employees of corporations, when they first enter the capitalist class, have such dreams. All honor to their ideals even though in nearly every case they have failed to make their visions realities.

Those who have are engaged in some business, hedged by patents and copyrights and free from labor agitation. Some others have managed to transfer their ideals to the field of operation, but they were in newly established industries where quantity production had not been attempted hitherto and where prices were, therefore, much higher than the nature of the product would warrant. But if Warren Stone wanted to be free of the stress of competition, if he wanted to make such profits that he could divide liberally with his employees and yet have usufruct for his toil and money, why did he attempt to go into the coal business? There have been years in the coal industry when such beneficence was possible, but 1924, as Warren Stone now recognizes, is not one of those years. At least the coal business in 1924 is not one in which that result can be attained. Probably the Brotherhood will realize that it will do well to enter industries which, like banking, employ little labor and have never known a union.

The mine workers have taken action against many of their numbers who have entered the troublous arena of life as capitalists. They have never escaped dissension and innuendo. Others have tried to act as combined workmen and capitalists, forming what is termed a "co-operative mine" and they have been threatened with expulsion from the union and practical boycott, because co-operation in gain means co-operation in loss, and so the men were soon working for what amounted to a concession in wages.

Stone has tried to be a capitalist with union money, and he is finding himself more handicapped than the mine worker who openly enters the capitalist class for his own gain. He has found himself facing both ways—a union man with regard to his brotherhood and a capitalist with regard to the United Mine Workers. The pipe dream has been nothing but rings of smoke. It cannot succeed, and it is likely that the unions may before long decide definitely that there is no halting between the union and Mammon, and that union men should cease to retain cards of membership as soon as they become capitalists.

---

IN ALL THE RECENT CHARGING and countercharging in the battles over child labor legislation, the coal mines of the country cannot after all, be accused of much offence. In spite of the pictures often drawn of worn, emaciated little boys toiling pitifully underground in coal mines, statistics of the 1920 census show that the total number of boys under 15 employed in all mining and quarrying was only 7,191. After deductions have been made for operations other than coal, there remains comparatively little child labor for which the coal industry can be held accountable.

# Advances in Mine Plants and Safety Are Themes of Coal Mining Institute of America

Nicholas Evans Elected President for 1925—Sayers Discusses Effect of Excessive Dust, Heat and Humidity—Dawson Relates Nature and Advantages of Colonial Conveyor System—Detailed Discussion of Rock Dusting

BY R. DAWSON HALL  
Engineering Editor, *Coal Age*

**L**ARGE numbers were down to the forty-eighth annual meeting of the Coal Mining Institute of America, at Pittsburgh, Pa., Dec. 3, 4 and 5, to hear about the belt conveyors at the Colonial Docks and about rock-dusting developments and to see the former working in the H. C. Frick Coke Co.'s mines and the dusting machines and dusted roadways at Indianola.

Business was quickly disposed of. The members learned from H. D. Mason, the secretary-treasurer, that the 2,661 members were increased by 350, due to new admissions at this meeting, bringing up the number to 3,011, that J. M. Armstrong, general manager of the Pittsburgh Coal Co., was responsible for bringing in more than one-half of the new members. They also learned that the finances were in better condition than ever in the history of the organization. They accepted the report on the Use-Classification of Coal and continued the life of the committee which reported, charging it with the duty of seeing that its recommendations be carried into practice.

The committee took Dr. Ashley's classification, modifying it only by using the percentages of volatile matter to the whole coal content on a moisture-free and ash-free basis. Dr. Ashley had favored allowing for 7 per cent of ash in the coal and estimating the volatile and fixed carbon so as to total 93 per cent, leaving a standard ash of 7 per cent. The committee viewed this as a somewhat artificial way of bringing the specifications to a comparable basis and not so productive of advantage as of misunderstanding, and decided to base the classification on an ash-and-moisture free basis instead, placing the dividing lines in the classification at even 7-per cent differences in volatile contents.

The tellers announced the election of Nicholas Evans as president, with 499 votes; J. M. Armstrong, first vice-president, with 463 votes; A. C. Fieldner, second vice-president, with 364 votes; W. C. Hood, third vice-

president with 315 votes; and H. D. Mason, secretary-treasurer with 566 votes.

M. D. Cooper, outgoing president, read an address on the "Positive Side of the Mining Industry," declaring that too much had been said about the faults and frailties of the business of coal mining and too little about its progress and about other qualities deserving of public approval. Other points he made were that greater continuity of operation was desirable and that this could be attained only by coal storage; that such storage was a matter rather for the consumer than the operator, for the latter could always produce enough to satisfy the consumer if the railroads could haul it. He said that storage serves the public best if done at destination rather than at the mines, despite the public's notion that coal should be stored where it is produced. He declared himself opposed to a Department of Mines. The creation of such an instrumentality, though it would elevate certain officials, would bring the Bureau of Mines into politics, of which hitherto it had managed to keep itself clear.

## KEEPING THE STANDBY LIMBER

Graham Bright then presented his paper on "Recent Electrical Progress in Coal Mining," which appears in this issue of *Coal Age*. W. L. Affelder, taking the chair for the discussion, Mr. Writh asked at what frequency and for what length of time should the standby unit be operated to be sure it always would be in condition for an emergency. He said that at a pumping plant in Oklahoma the standby was tested once a week for three minutes and it had been found possible to get the emergency unit operating in one minute from the supposed moment of breakdown of the regular unit.

Mr. Bright said he did not know how often the Youghiogeny & Ohio unit was tested but that when the mine was running, the emergency unit was operated at frequent and regular intervals. Asked by Mr. Affelder as to the cost of an installation such as that of the Youghiogeny & Ohio, he said that there were some refinements in the design of the standby engine that were hardly necessary, he thought, for a plant the

NOTE—Headpiece shows C. H. Dodge, research fellow on dusting, taking a sample in the No. 8 mine of the Pittsburgh Terminal Coal Co. The dust clinging to the ribs and roof in a strip 6 in. wide is carefully collected. About  $\frac{3}{4}$  lb. of that portion of the dust that will pass through a 10-mesh screen is put into one of the containers shown on the bottom and constitutes a sample.

operating economy of which was not a vital or even an important point. Such a plant with less elaboration but sufficient for all purposes could be constructed for \$6,000 to \$7,000.

H. J. Evans, of the Mather Collieries Co., said that his company's steam-engine standbys used only about 80 tons of coal a month. They did not require the services of a single man, for the power-house attendant kept the boilers fired. He said that the cost of the standby plant, which was built originally for the operation of the hoist and fan, was more than \$25,000. The emergency unit could be gotten into line in four or five minutes and with it men could be hoisted and the fan operated.

J. J. Rutledge, chief mining engineer, State of Maryland, said that in the Dolomite disaster the emergency equipment was brought into operation within seven minutes after the explosion. It undoubtedly saved many lives. It cleared the mine in a short time.

W. L. Affelder said he did not want to suggest to the mine inspectors what they should do, but he believed it might be well for them to require the testing of auxiliary equipment at mines when visiting a coal plant, just as some of them were requiring a test to be made of the overwind devices.

W. L. Maize said that when the Nemaquin mine took out its seven boilers and put in purchased power it laid off no less than sixteen men who in the course of twenty-four hours were employed at the boilers of that plant. He fully realized what it meant to maintain a steam standby.

In answering Question No. 1, which inquired why the Pennsylvania bituminous mining law demanded that "For work underground when supplied by current at voltage higher than medium voltage no transformer shall have a normal capacity of less than 5 kw., nor shall any motor have a normal capacity of less than 15 hp." Mr. Bright said that with 2,200-volt alternating-current the wire would be so small that a reliable motor or transformer could not be made. This was the objection from a manufacturing standpoint. Viewed as a mining matter, he would say that equipment so small would be regarded with more or less indifference and therefore might be neglected. Mr. Bryan remarked that where 440-volt alternating current was used for transmission the requirements as to size seemed too small.

#### CONDEMN 500-VOLT CIRCUITS

The question whether a voltage of 500 is reasonably safe for all working conditions in 3½ ft. of coal developed no conflict of opinion. Joseph Williams, Nicholas Evans, W. L. Maize and William Langan agreed in condemning it, wondering, however, if anywhere it was used in places as low as 3½ ft. R. N. Hosler said that four out of five electrical accidents came from the use of 500-volt circuits. He considered that this was sufficient evidence of their dangerous quality. William George, Madeira Hill Coal Mining Co., said that while a shock from a 250-volt current tends to knock one away from the circuit, a 500-volt circuit tends to hold you to it.

R. C. Beerbower said that on the opening of the Springdale mine there had been much discussion in his company as to the better voltage to use—250 or 500. As a result it was decided to use 250, the mining men vigorously protesting against the arguments of the electric power plant experts who favored 500 volts. He felt that it was the economical voltage because the ma-

chinery was more readily maintained in condition. Joseph Knapper said he had no more accidents where 500-volt circuits were established than where the voltage was 250. The men apparently had become educated to take no chances with such deadly current. Nevertheless he was opposed to so high a voltage. W. H. Howarth said that as the lower tension was likely to be made legal it was risky financially to install a higher tension.

At the afternoon session Alexander McCanch, state mine inspector at Monongahela, Pa., gave well-considered views of "Mine Accidents and Their Prevention." In commenting on Mr. McCanch's paper, F. B. Dunbar, general superintendent, Hillman Coal & Coke Co., said there always should be clearance on both sides of a mine

Nicholas Evans

For many years state mine inspector of Johnstown, Pa. Elected president, Coal Mining Institute of America for 1925. Mr. Evans has for many years been a member of the Coal Mining Institute of America and a regular attendant.

track—a wide or working clearance on one side and a man-clearance on the other. He said also that firebosses should be encouraged to report gas. Twenty years ago a fireboss would be discharged in some mines if he reported gas twice in the same section. It was an attitude like that which caused the fireboss to fail to report gas and this, in those days, was a cause of many accidents.

R. N. Hosler said that one-third of the men killed in haulage accidents were not employed in haulage, showing the need for separate travelingways for mine workers or for the introduction of the man-trip. Francis Feehan declared that the mine workers were quite frequently sent into the mines without being directed as to safety practices and without having it clearly understood that safe conduct at the mines was a condition of employment. He believed that men should be disciplined for infractions of the mine rules.

C. L. Lutton, of the H. C. Frick Coke Co., in reply to Mr. Feehan said that a colored man related at a safety meeting that he hadn't learned much about mining, but this he had learned that he must block his cars. He had lost a week on suspension, and the idea was clearly borne in on him that it was an excellent thing to do if one desired to hold one's job with the H. C. Frick Coke Co. George Steinheiser, general

superintendent, Jefferson & Clearfield Coal & Iron Co., believed that prosecution was the better way to enforce safety and asked, "Can you prosecute a man for disobeying safety provisions when the violation of the rules does not produce an accident?"

Mr. McCanch declared that a man could be prosecuted for a violation of the mining law but not for failure to comply with the orders of the foreman if those orders required him to do something that would promote safety but which was not a legal requirement. Thus the track in his room might be in such condition as to be likely to cause an accident. The foreman might order him to repair or relay the track. That was a proper order, but compliance with it was not required for the miner under any provision of the law. The foreman could discharge the man for failure to comply with the order, but he could not prosecute him, no matter how much his negligence might menace life or limb.

Mr. Steinheiser replied that he questioned whether the foreman could prosecute a man for failing to set a prop on being ordered to do so. Mr. McCanch said he had obtained the conviction of a man for that act of negligence, but it was necessary to show the court that the condition of the roof made the standing of a prop necessary for safety. John I. Pratt said that he knew of an instance where a foreman had ordered a man to stand a prop. When the man failed to do as directed, the foreman ordered the man to leave the room, and he then put a danger signal near the room mouth. He prosecuted the man for the act of disobedience, and the court found as requested, fining the man \$100.

#### SUSPENSION MORE EFFECTIVE

W. G. Duncan declared that in a number of cases it had not been necessary in obtaining conviction to show that an accident had occurred. You cannot, he said, derive the whole law from any one paragraph. There are some unsafe practices for which a man can be prosecuted with or without an accident and others for which a man can be prosecuted only if an injury follows. A. C. Callen said that for some violations of the orders of a mine foreman mine workers cannot be convicted, and it is questionable whether they can be sentenced for not setting a post when ordered, if the roof is strong and sound. But "Why," said he, "prosecute a mine worker when suspension gets quicker results?"

H. E. Kinlock questioned the advantage of having miners set timber. He had gone to work in the mines in 1871, and in the mine in which he was employed, even in that early day, timbermen set all posts. Joseph Knapper said that the Secretary of Mines had this year pitted the anthracite mines against the bituminous mines in a contest for safety. The anthracite mines usually have one-fifth more fatalities per thousand men employed than bituminous mines. This year the latter, though they had worked irregularly, had experienced more fatalities per thousand than those in the anthracite region.

Dr. R. R. Sayers then delivered an address on "Health Hazards in the Mining Industry," describing the effects of high temperatures and humidities, of dusts, of oxygen depletion, of carbon dioxide, hydrogen sulphide, sulphur dioxide and carbon monoxide. He discussed also the methods employed underground for disposing of sewage and providing drinking water, the value of illumination and the diseases known as nystagmus, beat hand, beat knee and beat elbow.

He described, though his paper does not report it, the sanitary conditions inside and outside the mines

Fear Rock-Dust Distributor in Operation

This type has been developed for use in thick seams. It has a carrying capacity of 3 tons of rock dust and with two men will lay a uniform coat of dust over one mile of entry in a shift of 8 hours. This photograph was taken in the No. 8 mine of the Pittsburgh Terminal Coal Co.

the experiments made on animals by injecting dusts in the abdomen, thus creating in the subject tissue changes probably similar in all respects to those created in the lungs by inhaling dust. The action is more rapid, however, and these inquiries seem to indicate that dust of many, if not of all kinds if introduced in quantity has its harmful effect. Dust is like poisonous gas. The human organism can resist even the most poisonous of gases if presented in sufficiently diluted form, but succumbs readily to a dose of greater concentration. He said that Dr. Mavrogordato has concluded that "it is the dust that cannot escape from the tissues which is a source of danger and as long as elimination follows fairly closely upon the heels of ingestion not much harm is done. Coal seems to set up a sort of aseptic 'catarrh' in which there is a steady exodus of particles from the lungs." In reply to N. D. Hubbell, Dr. Sayers said that amorphous silica, such as kaolin, like crystalline silica, was harmful, at least when injected into the abdomen.

In response to an inquiry as to whether nystagmus might be a germ or worm disease transmitted in warm mines he said that men in clerical work with poor illumination often suffered from nystagmus which passed away when the working light was bettered. Some have thought, however, that nystagmus might be caused by gases. The victim of nystagmus at first carried, in the eye, images of things he had previously seen—after images—and later had oscillations of the eyeball, vertical or horizontal, usually the former.

#### COAL DUST CURED TUBERCULOSIS

Nicholas Evans said he questioned whether coal dust could be harmful to the human organism. He knew of a tubercular man who went to work at a coal dump to get his fill of coal dust; in consequence his tuberculosis was cured.

Dr. Sayers said that he thought that the claim that the presence of coal dust enabled the lungs to throw off dust cells was rather far fetched. It had, nevertheless, its advocates. Asked by J. F. Downs whether a man whose heart missed beats while working in a place where carbon dioxide was present in excess of the normal quantity, could ascribe the condition fairly to the presence of that gas, Dr. Sayers said that with such quantities as were likely to occur such an effect on the heart would be unlikely. He would want to know what the man was doing in the off-shift hours.

Questions Nos. 3 and 4 were combined to read "Are

much improved over thirty years ago? If so, what are the main reasons?" Dr. Sayers said that there was no doubt that conditions are now more favorable. Better air and water were provided. J. J. Rutledge said that the air had greatly improved since the time when it was said that the way to make an old man out of a young one was to put him at work driving entry. He thought all mines needed the man trip and the change house. However, to H. E. Kinlock, who in 1871 went to work in a mine where brattices were kept within 4 ft. of the face and where all the shooting was done at night, it appeared that conditions were worse than in years past.

In response to an inquiry, Dr. Sayers declared that burned-out carbide residue did no harm. Some silicon hydride might be emitted and this gas was dangerous like hydrogen sulphide, but occurring in small quantities it did no harm.

At the banquet, with M. D. Cooper presiding, the Rev. Dr. Frederick G. Budlong made an address on "Leadership"; Thomas S. Baker, president of the Carnegie Institute of Technology, one on "Engineering Education" and H. L. Cope a humorous address on the philosophy of laughter. Dr. Baker said that the large consolidations in industry restricted the number of places open for college graduates, but also made the few places available of more value for those who obtained them. He also said that the many specialties developing tempted the colleges to go too far into specialized education. He added that it seemed likely that, in order to give a student the material needed for meeting the problems of operation, the courses might have to be lengthened.

#### BELT CONVEYOR 4½ MILES LONG

At the morning session of Thursday, Ralph Beerbower, general manager, Pittsburgh-Allegheny Coal Co., presided, the session opening with an address by Thomas C. Dawson, chief engineer, H. C. Frick Coke Co., on "Underground Belt Transportation of Coal." In this address Mr. Dawson described the 4½-mile belt conveyor of the H. C. Frick Coke Co. at Colonial mines, which was to be visited the following morning. Mr. Dawson also showed moving pictures of the installation.

M. A. Kendall, chief engineer, Stephens-Adamson Manufacturing Co., read a paper on the same subject, giving details regarding the four belts of the Hardy Coal Co., at Panther, W. Va. He remarked that though the longest belt at the H. C. Frick Coke Co.'s installation was 1,513 ft. long his company was of the opinion that the distance between centers could be economically and safely extended to 2,500 or even 3,000 ft. The tensile strength of the belt at the Frick plant was 10 to 12 times the working strength. The energy consumed was 0.1 kw.-hr. per ton-mile on the level. There was practically no dust, though to obtain that condition the coal was watered at the face.

E. C. Auld, the mechanical engineer of the H. C. Frick

Coke Co., discussed the plant and said that there was practically no disintegration of the coal. W. L. Affelder wanted to know if the product had not deteriorated as a result of the use of the long rotary dump which made inspection of each individual mine-car load of coal practically impossible. Mr. Auld said that the Clairton furnace had made no complaint of that sort.

Means are afforded for slowing down the dumping of coal, so that it can be inspected as it is being discharged. Tracks are provided by which a full trip can be set aside for that purpose. This trip can be dumped slowly and the coal watched as it leaves the cars. Should the coal from any section of the mine be suspected of having an abnormal percentage of ash, it can be side-tracked and examined at leisure.

In reply to M. D. Cooper, Mr. Auld stated that the accident rate had not increased as a result of the installation of the belts. Inquiry developed from Mr. Auld that no accidents had occurred in the operation of the belts, but that their installation had not reduced accidents because the coal prior to the operation of the belts traveled as far as it does now.

The coal formerly was not carried to the river but was discharged and used at points four miles or more from the docks. The system, however, increased the safety, as the cars were not uncoupled before dumping and did not have to be recoupled thereafter. No accidents had occurred while the idlers were being removed from under the moving belt for repairs. T. W. Dawson said that 1,000,000 tons had passed over the belt since its installation April 1.

#### NO COAL BROKEN ON CHUTES

In answer to an inquiry, Mr. Auld said no careful examination had been made, but he believed that no coal was broken in sliding on the chutes from one belt to the next in line. Some breakage occurred in falling into the bins and again in loading the coal into barges from the pockets at the docks. At the feeders, the coal falls on coal, the layer of coal being built up as the belt under the feeders progresses along the dump.

In answer to Question No. 6, "Is Underground Mechanical Loading a Success?" R. R. Dunlop read the paper of N. D. Levin, chief engineer, Jeffrey Manufacturing Co., on the new loading and belt conveyor methods of his company. He said he had in mind developments of this kind for twenty years, but felt sure they were foredoomed to failure so long as operators insisted on maintaining their present room-and-pillar methods. Now that the longwall system is receiving tardy recognition his company is preparing to supply the necessary machinery.

His view was that the machines for loading should not be moved from place to place several times in a single shift; in fact he declared that the machine should remain in a single place, shift after shift, till the place was worked out. Mr. Levin said that the New

River Co. at its Cranberry mines with head offices at McDonald, W. Va., had a shortwall conveyor with a sectional conveyor at work and also a shortwall loader with sectional conveyor. Five blocks, 100 ft. wide by 100 ft. long, had been removed already.

He did not know, as yet, whether it would be found that the two upper cutterbars broke the coal to such a degree as to increase the percentage of fine coal. He thought not. The speed of the upper cutterbars was slow. With this device the coal could be shot lightly, far lighter than with other methods of loading. The machine could load coal even when the seam had been shot so lightly as just to shake or crack it without, however, bringing any coal to the floor.

Mr. Maize, state mine inspector, said that the main difficulty of the inspectors was to keep loading machines out of the mines. Operators inform them that they are going to put loaders to work and inquiry develops that the operator has not troubled to ask whether the loaders are flameproof. He wondered that the manufacturers of loading machines overlooked the importance of fitting them for use in gaseous mines. Mr. Levin said the motor on the 44-A loader had been approved by the Bureau of Mines. No official approval had yet been accorded the other loader, but they expected to receive it soon.

E. H. Coxe, general manager, Snowden Coke Co., said that he had been trying to work his coal by longwall. The main roof could be held satisfactorily, but the drawslate was giving much trouble. He could not hold the roof for a distance of more than 4 ft. from the face. He could make his 6½-ft. undercut, but the roof had to be posted as soon as the cut had been made.

#### MOVIES SHOW DUSTING METHODS IN WEST

At the afternoon session, over which R. N. Hosler presided, Edward Steidle, supervisor, co-operative courses, Carnegie Institute of Technology, read his paper on "Modern Methods of Rock Dusting in Coal Mines," the first part of which is published in this issue. H. I. Smith said that rock dusting was advocated by George S. Rice a third of a century ago. Mr. Rice told an operator in Illinois that explosions had been found to terminate in places where there was a large quantity of shale dust, and that he thought the artificial spreading of such dust would act as the natural dust had done. Later the Rainey mines had been dusted and one of the mines of the Pittsburgh Coal Co. Mr. Smith showed motion pictures of a trip he had taken with J. E. Jones through the West. They found that the Western mines had actively entered the rock-dusting campaign and devised several dusting machines for use in their entries.

J. T. Ryan also showed several pictures of the Bureau of Mines' barriers, the Fear rock-dusting cars and the Indianola mine. Mr. Fear said that the cost of rock dusting at his mine during the month of May was 7 mills per ton. He expected it would be less hereafter. His final machine had a large dusting capacity, but in practice, as there were delays, it would be likely not to average over 4,000 lineal feet a day.

He found that the finer dusts did not stick on the sides of the roadway not having, he believed, sufficient inertia, so he was going to use dust that was somewhat coarser. Dr. W. J. McConnell, of the Bureau of Mines, replying to Question 8, said that limestone was the preferable material for rock dusting because of its light color, its freedom from combustible and its probable

physiologic harmlessness. Shales contained usually from 2 to 20 per cent of combustible matter.

J. M. Armstrong, general manager, Pittsburgh Coal Co., said that rock dusting had cost them 2½c. per ton of coal mined but that he hoped the cost might be reduced to 1c. He doubted if the Pittsburgh Coal Co. would be able to reduce the cost below that figure. Mr. Dunbar, general superintendent, Hillman Coal & Coke Co., said that his company had dusted about 60,000 ft. of entry. It was using barriers where there was no road. He had never thought much of water sprinkling. Most managers did just enough to "get by the inspector." He believed that rock dust would not

**J. M. Armstrong**

General manager, Pittsburgh Coal Co., elected first vice-president Coal Mining Institute of America for 1925. Mr. Armstrong's efforts this year brought 161 new members to the institute.

only protect the mine against explosions but also against the slabbing of the pillars along the roadway.

A. C. Fieldner described the volumeter. Coal dust has a specific gravity of 1.3 and rock dust, whether limestone or shale, a specific gravity of 2.6 approximately. Twenty grams of collected dust are put in a receptacle and to it are added 50 c.c. of liquid. The level of the liquid is then read. Some kind of alcohol is used because alcohol will wet coal dust whereas water will not. Thus the dust will fail to receive the water into its interstices. If there is much coal in the dust a greater volume of dust would have to be used to provide the required weight (20g.) and the liquid will rise to a higher level in the volumeter. This method of determining the inertness of rock dust was suggested by M. Taffanel, the French mining expert.

Samples of dust from all over the country had been tested by this and by combustion methods, and no differences exceeding 5 per cent had been found in the indications by the two methods. In burning dusts if limestone is present not only will the combustible be burned away, but the limestone will be decomposed, giving excessive indications of "combustible." Conse-

quently, without great care to correct for this decomposition, the combustion method will give errors larger than those given by the volumeter method. Mr. Fieldner added that in France a method of measuring the inertness of mixed dust by the length of the flame produced in its combustion was practiced. He found it difficult to ascertain the length of the flame and, though he believed the ability to do so could be acquired, it would take long training and even then the method would be inexact and somewhat fortuitous.

Mr. Steidle said that he could not grant that there was any danger to health to be anticipated from the use of dust containing 35 per cent of free silica. Such dust had been used in Great Britain for years without unfavorable results. In Illinois dust of that character had been employed for three years.

Mr. Rice referred to the discovery, by Mr. Atkinson in England, that the presence of disintegrated rock dampened the violence of explosions, to the rock dusting work of Dr. Garforth at Alltofts and to the erection by that mine manager of a short dust gallery for experiments. He said that when he was traveling the mines of Great Britain he had never seen the dust rise in a cloud from the roadway except when a horse was hauling cars along the road. Then the dust would rise knee high, but above that the air was clear.

#### BARRIERS STILL GOOD AFTER A YEAR

Dusts from all over the country had been sent to the Bureau for test. Some were extremely bad, especially flue dust, which the Bureau had condemned. Despite all that had been said as to the packing of ground rock in the presence of moisture, the rock dust in the barriers at the experimental mine had remained in good condition for a year at a time, showing that some dusts at least did not harden in a short time and become valueless. About 90 per cent of the time the barriers proved effective but in 10 per cent of the cases they failed. Perhaps he might be pardoned in speaking about the Dawson explosion that occurred many years back. At that operation were two distinct mines connected by a passageway. The explosion in one mine communicated to the other, and a large number of men were killed in the second mine. A rock-dust barrier probably would have prevented the passage of the explosion from one mine to the other. Mr. Rice added that before he went to France on his recent trip an operator called him in consultation and told him he wanted to get the latest information on rock dusting. This operator said sprinkling was costing him 25c. a ton and that he had ordered the management, nevertheless, to spare no expense, but he wanted a cheaper and more assured way of obtaining safety. He is now using rock dust.

Mr. Enzian said several companies in central Pennsylvania were getting ready to rock dust. Others said that rock dusting was either being introduced or had been introduced at Wehrum, Robindale and Nantygly.

In discussing Question No. 9 as to "The most effective way of minimizing the present appalling rate of fatalities due to falls," Mr. McCanch said that overdevelopment of mines should be avoided because when roadways were allowed to stand the rock became loose and was likely to fall. Of course, it was necessary in places when the measures were uncertain to keep the development well in advance, lest at any time it might be found that a certain area would yield no tonnage and consequently that provisions should have been made to open up an entirely different area.

On Friday at least two inspection trips were made, one to Colonial docks and the other to Indianola. The visitors to the former inspected the dump and then were taken in cars along the belt-conveyor line to the rotary dump where the first belt is loaded with coal from the mine cars, thirty-five to forty cars being dumped at one time. As Mr. Dawson described the plant quite completely in his paper it is not necessary to discuss it at length. It might be well to emphasize the freedom from dust throughout the operation.

In many places the old Alice mine, used as the approach to the Colonial mine, had caved to considerable heights, and it had been necessary to build arches over the entry. Large quantities of concrete, steel posts and steel beams have been used to protect the roadway, which in the Alice mine is 14 ft. wide. The coal is taken by the belts to a bin under which move two shuttle conveyors. Each conveyor can handle 1,000 tons per hour. They move backwards and forwards so that the point of discharge is varied. Each storage bin has a capacity of 1,200 tons. Barges, 26 ft. wide by 175 ft. long and carrying 850 tons are loaded by eight chutes and can be filled in ten minutes. All gates, chutes and the barge-mover are controlled from the operator's room under the bins. Lunch was served to the visitors by the H. C. Frick Coke Co., in the supply house of the mine.

R. C. Beerbower supervised the trip to the Indianola mine which was accomplished in automobiles. The Westinghouse Electric and Manufacturing Co. prepared an interesting exhibit at East Pittsburgh, showing a new permissible mining machine, a new arc-welding rheostat, a 200-amp. arc welder, clutch-type synchronous motors, a pneumatic hoist control, die-cast aluminum rotors for squirrel-cage motors, sealed sleeve bearing for motors and other interesting exhibits.

#### Crush Their Own Stone at Paintsville, Ky.

Many coal mines produce a good grade of sand rock which can be broken up advantageously for tramroad and railroad ballast, for concrete and for village road improvements. At Thealka, Ky., the North East Coal Co. has erected a bin and purchased a stone crusher and elevator for the preparation and storing of stone to be used in their concrete construction work. This is located at the foot of the slate pile, the sand rock being slid down the face of the dump by means of a rudimentary chute.

Stone Crusher at Paintsville, Ky.

A portable crusher, an elevator and a roofed bin form a suitable plant for the crushing of sand rock and its storage preparatory to use for concreting. The North East Coal Co. has found this rough equipment of great use in reducing its concreting costs. much concrete work being used in the mines and around them.

# How Rock Dust Cures the Epidemic of Mine Explosions

Explosions' Fatalities Rise in 1924 to 25 per Cent of All Fatal Accidents in Mines—One Hundred Companies or More Are Now Rock Dusting—Some Rock Dust on All Roadways, Ribs, Roof and Timbers

BY EDWARD STEIDLE

Superintendent Co-operative Mining Course,  
Carnegie Institute of Technology,  
Pittsburgh, Pa.

AMERICA has experienced its full share of bituminous coal-mine explosions. The first on record in this country occurred on March 18, 1839, in the Black Heath mine near Richmond, Virginia, and resulted in 40 fatalities. Up to Nov. 1, 1924, according to reliable data, there have been 263 explosions in the bituminous mines of the United States, killing five or more men each, or a total of 7,735. The largest disaster took a toll of 361 lives.

Beginning with 1910 and ending with Dec. 4, 1924, there have been 58 explosions in which coal dust is known to have played an important part, with a total loss of 2,422 lives, to say nothing of millions of dollars in property. It is estimated that about 75 per cent of the lives lost in coal dust explosions could have been saved if the mines in which the explosions occurred had been systematically rock dusted.

It must be remembered too, that the majority of mine explosions occur when relatively few men are in the mine. In so far as the time element is concerned, the two high peaks for explosions are at 7:30 a.m. and 6 p.m.; the former is due in large measure to poor fire-bossing, or open lights (which means gas) and the latter to shotfiring (which means explosives and dust).

## EXPLOSION HAZARD MAGNIFIED

The figures mentioned look big, but it is true that normally, on a percentage basis, the explosion hazard is of minor importance. Over a period of 10 years from 1911 to 1920, inclusive, only about 12.21 per cent of the total number of fatalities in the bituminous coal mines was due to explosions and fires, whereas 41.19 per cent was due to falls of roof and coal. From another angle it might be added that the average number of men killed per 1,000 full-year (300-day) workers during this same 10-year period is less than 5, which means about 0.6 killed by explosion and fires per 1,000 full-year workers. On a million-ton basis this figure

would be even less. Therefore, the glaring headlines in the press, following a mine explosion are uncalled for and mislead the public, which can do little to remedy the evil, but is only too free to criticize.

However, if we consider the explosion record since 1920 we can readily appreciate why mine owners, mine workers, and the public are deeply concerned in the matter. Five explosions occurred during 1920 with an average of seven fatalities per explosion, eight explosions with an average of four deaths in 1921, seventeen explosions with an average of sixteen deaths in 1922, seventeen explosions and an average of twenty deaths in 1923, and eight explosions resulting in a total of 452 fatalities in 1924, up to and including Oct. 1. The percentage of the total number of fatalities due to explosions and fires has already jumped up from 12.21 to about 25 per cent in 1924. This is the tragic story of the past four years, and the cause for the feeling of alarm among our responsible coal mining men, who can and will improve these conditions.

## COMPARATIVE COST NEGLIGIBLE

Several of our leading mining men who have had experience in rock dusting believe that on a long-term basis the cost of applying rock dust will not exceed a quarter of a cent per ton of coal mined but obviously this figure has not been substantiated. In any event the cost should not exceed 1 cent per ton. However, any reasonable expense is an almost negligible item as compared with the loss of life and property. The cost to the public of widespread coal dust explosions is many times greater than the cost of preventing these explosions by rock dusting. The Castlegate and Benwood explosions are reported to have cost no less than \$2,000,000 in compensation, property damage, and recovery costs.

If 500,000,000 tons of bituminous coal are produced in 1924, this loss represents an added cost of 0.4c. per ton that in the last analysis must be paid by the consumer. In other words, the money lost by these two widespread explosions, which could have been prevented by systematic application of rock dust, would possibly have

NOTE—First part of paper entitled "Methods of Rock Dusting Bituminous Mines," read before the Coal Mining Institute of America, Pittsburgh, Pa., Dec. 4. Headpiece shows safety inspector ascertaining the percentage of inert material in the dust from the mine.

rock dusted all the dry and dusty bituminous coal mines of the United States without increasing the total cost of coal for the year.

Bituminous coal mining operators do not knowingly and willingly allow potential explosion conditions to exist in their mines. Operators and officials are just as humane as mine workers and always guard against the horrors of an explosion. Yet the record just given is circumstantial evidence that there are evils of omission or commission, or both, on the part of someone. By an act of Congress, approved May 16, 1910, and effective July 1, 1910, a Bureau of Mines was established in the Department of the Interior. At first the Bureau, under the terms of the act, gave attention chiefly to investigation of causes of, and remedies for, accidents, especially coal mine explosions. With a view, therefore, of eliminating explosions from the miner's life and from a critical public, the characteristics of gas and coal dust explosions have been studied diligently by the Bureau since 1910. The scientific facts so ably established by the Bureau are sufficiently extensive to justify the expectation of a better history than the record shows. The Bureau has of course no mandatory power and does not wish to obtain it.

However, at least ten years ago, the Bureau recommended rock dusting among other things as a means of preventing and limiting mine explosions. Only five operators adopted the system in America up to 1924. Therefore, some mining men were either not fully informed regarding these preventive measures or did not give them proper weight in the conduct of their business. In due fairness it should be stated, however, that a few of our more serious explosions have occurred in mines where nearly every practical and physical precaution had been taken, only to be nullified by a false step on the part of some employee or by defective equipment.

#### WATERING METHOD COSTLY

Coal dust can be made harmless if it is wetted so that it cannot be thrown into suspension. Watering is the method which has been most commonly used, and to a limited extent successfully, but it is costly, deceptive and usually gives a false sense of security. For some years during the early days of the Bureau of Mines, humidification of mine air was considered to be the panacea for widespread explosions, in that it would allay the dust, but tests conducted by bureau engineers showed that humidification was not a satisfactory remedy. In our present enthusiasm over the use of rock dust, the good work that various mining companies throughout the country have done in wetting down coal dust and in humidifying mine air should not be overlooked. But at a number of mines where water was used consistently, violent and widespread explosions have occurred.

Up to June 17, 1924, only five companies were rock

dusting in America. But this safety measure has received a great impetus during the past six months. At least one hundred mining companies have adopted rock dusting in various parts of the country, and it is being taken up much faster than anyone anticipated. However, as usual among coal mining men, it is being done quietly and with due deliberation. One large company in the Pittsburgh district is systematically rock dusting eight of its mines, but no publicity whatsoever has been given to the matter. Mine operators are in earnest regarding the rock dusting of their mines, and the "boom" will naturally extend over the next two or three years.

In this connection the Carnegie Institute of Technology, in co-operation with the Bureau of Mines and the Advisory Board of Mine Operators and Engineers in western Pennsylvania, is carrying on fellowship researches relative to rock dusting during the present college year. It is endeavoring to devise a more satisfactory method of quantitative analysis for free silica, using microscopic means and to determine which rock formations associated with the coal measures in western Pennsylvania are suitable for rock dusting. It will collect data relating to costs, equipment, and systematic methods of treatment, particularly regarding the Pittsburgh Terminal No. 8 mine which is being rock dusted in an

up-to-date manner, and where accurate and detailed costs are being kept. A bulletin covering the results of these investigations will be ready for distribution in the early fall of 1925.

During the past ten months much has been said and written regarding rock dusting. In this period we have had considerable experience and, as usual, many of our theories have necessarily given way to practical considerations. We are just beginning to get at the bottom of the practical application of rock dusting, and one of the first conclusions is that rock dusting is truly an engineering problem. Sooner or later the Bureau of Mines will have to prepare a schedule of tests for rock dusting equipment. My endeavor in this paper is simply to point out some of the more practical phases and modern developments relative to this means of explosion prevention.

#### SAVES INSURANCE COMPENSATION

In June, 1924, the Coal Mine Section, Pennsylvania Compensation Rating and Inspection Bureau, revised Item 85 of its Rating Schedule so that a charge of 5c. is made for a dry and dusty mine, and at the same time a credit of 10c. is given where the mine is rock dusted. In other words, a properly rock dusted mine in Pennsylvania will save 15c. per \$100 of payroll in its compensation insurance. It might be added that Illinois, Indiana, Iowa, and Michigan allow a credit of 10c. for rock dusting. Kansas and Montana give a credit of 13c., and Utah a credit of 14c., while New Mexico, Ala-

### ALREADY ROCK DUSTED BUT INSUFFICIENTLY

**E**XAMINATION has shown that in an undusted mine the road dust is as an average 43.5 per cent inert, ranging between 27.2 and 54.6 per cent. The dust on the rib, roof and timbers averages 30.8 per cent inert with a range between 20.7 and 50.1 per cent. Thus all roadways are rock-dusted in a degree, but dust explosions show how greatly that natural treatment fails to be adequate. Still, we may be encouraged by the fact that some of the needed work is done automatically, and our work is merely supplemental to what is already done. Physiologically also we are gratified to learn that we are not adding 50 or 60 per cent of dust but a much smaller quantity to what we already have on the roadway.

**Safety Inspector Waiting to Descend Shaft**

He has hanging from a strap in his right hand a number of cartons for holding his dust samples. He carries also his lamp, battery and the means for sampling the dust. No elaborate outfit is required.

bama, Colorado, and Oklahoma head the list with a credit of 20c.

One steps into deep water when one discusses legislative matters. However, it is desirable to mention at this time the attention being given by various states to rock dusting and other preventive measures. A number of states propose a revision of their mining laws with regard to the coal dust hazard and rock dusting. During the last session of Congress, Representative John N. Robison, Chairman of the House Committee on Mines and Mining, suggested in a speech before the House of Representatives that the President should call a conference of Governors of coal producing states for the purpose of considering joint uniform action relative to safety measures in mines, including rock dusting.

Recent drastic Federal and State regulations approved by mine operators made rock dusting compulsory in the bituminous coal mines of Utah, beginning July 1, 1924. Legislative action favorable to rock dusting may be expected, furthermore, in other states. Colorado has already proposed legislative action, and Pennsylvania, Maryland, Washington, and West Virginia are now giving the matter due consideration. If we are to have new legislation it is, of course, essential that the various states know what they are about and then, if possible, work for uniform regulation.

Some mining men believe that we have too many mining laws, and that some of them need to be removed from the statute books and better ones standardized and substituted. Other men feel that supplementing statute laws with regulation, as is done in Maryland, Wisconsin, California and Utah, is the best way to cover these matters. Some men say that we have sufficient law, if it is enforced, and we need to put some regulation into effect. If the rock dusting problem is handled properly and it proves to be entirely successful, no mining man of any standing will delay its use in his mine. State legislation regarding this matter may or may not solve the problem. In other words, every

mine in the State of Utah is being rock dusted, and though some are doing it conscientiously, with intent to get what good can be obtained, others are reported to be doing it only to keep within state regulation.

It has been proved conclusively that if pure, fine, dry coal dust is raised into a cloud in the presence of a source of heat—for example, a blownout shot, an ignition of gas, or an electric arc—combustion takes place between the carbon and hydrogen of the dust and the oxygen of the air. This reaction may continue, and the flame travels or propagates through the dust cloud with rising temperature and increasing velocity and violence. One outstanding feature is the fact that bituminous coal dust is flammable in pure air. The presence of an explosive gas may aid, but is in no way required for a coal dust explosion. Explosions are sure to occur when there is a proper combination of conditions, and it is well understood that the season from, say, August to March, is always far more prolific of dust explosions than the remainder of the year.

When not less than a 50-50 mixture of rock dust and coal dust is thrown into suspension, the rock dust, together with the coal dust, absorbs heat and lowers the temperature of the flame of propagation below the ignition temperature of the coal dust. Also the particles of rock dust get between the particles of coal dust and have a curtain-like effect. One of the most reasonable merits of rock dusting is the fact that once the dust is distributed systematically throughout a mine, it remains there indefinitely and is always "on guard" during the dangerous period of the year.

It should, of course, be definitely understood that rock dusting is only an additional precaution, and is not expected to take the place of any existing practice of keeping the mine well ventilated and as clean of coal dust as is possible. In other words, mining men will not tie absolutely to rock dusting. It is entirely satisfactory for haulage entries and entry aircourses, but it may be desirable to "kill" the coal dust as it is in process of formation, or immediately afterwards and particularly in dry and dusty mines.

#### WATER USED AT WORKING FACES

The way some companies are doing this is by using water and plenty of it, at and near the working faces; for example, on machine cutter bars while undercutting, in the immediate vicinity of the face before blasting, and on the broken coal before and while shoveling. On the other hand some mining men believe that watering at the face is of no consequence as well as impracticable, and that sprinkling merely agitates the dry, fine dust. Others state that analysis records of samples taken before and several months after washing down the gob, indicate that the dry, fine dust before washing actually contained a greater amount of incombustible.

The production and accumulation of fine dust also can be eliminated in a large measure at the working face by driving all workings on sight, so that a minimum number of bumps will be left to be pick-mined; by more careful handling of bug dust; by loading out all bug dust in the beds of cars; and by more efficient use of explosives. On haulage roads the production of fine dust can be reduced by using tight-fitting and solid-body cars; by employing stiff hitchings; and by providing a well constructed track.

Some companies sprinkle loaded cars after they are loaded and before they leave the face, and also spray them as trips are leaving inside switches or partings.

The cost of drastic safety measures seems, on first thought, to be prohibitive, but our mines should be made safe, and any expense in this connection logically can be charged to the consuming public.

Coal mining men are now thoroughly convinced of the value of two safety measures—namely, the use of permissible explosives and of electric cap lamps. However, only 33 per cent of the coal mined in 1923 when bituminous production was 545,000,000 tons, was shot by permissible explosives. The number of electric cap lamps in use at the present time is estimated at something over 200,000, and is growing. Rock dusting and these other safety measures are important indeed, but it must not be overlooked that most mine explosions have had their beginning in gas accumulations and frequently originated in restricted areas at the working face, in abandoned areas or at some other place where ventilation is not maintained as it should be.

There must not be too much "rule-of-thumb" relative to the volume of air required and constantly furnished at a given working face or in a given entry panel or other area. The question uppermost in mind is whether a sufficient quantity of pure air reaches every portion of the mine, brushes all fresh working faces, and the shifting top in pillar-drawing areas. An accurate ventilating map and definite records of air at the face must be kept as well as barometric observations. It must be remembered also, that for each 1 per cent of methane in the mine air an increase in quantity of rock dust of 5 per cent will be required.

The Bureau of Mines seems to have established the fact that coal dust is flammable in proportion to its fineness and dryness, and to the proportion that the ratio:

$$\frac{\text{Volatile matter}}{\text{Fixed carbon} + \text{Volatile matter}}$$

This ratio indicates that anthracite dust is practically non-explosive, that fine dry bituminous and lignitic dusts are highly flammable, and that dust of such a hydrocarbon solid as gilsonite is almost as explosive as gunpowder. Furthermore, it is established that bituminous dust which is larger than 20-mesh will scarcely enter into an explosion. One which is about 100-mesh is dangerous, especially if dry, and one which passes

Quartering the Dust for a Sample

As the quantity of dust removed from the floor or ribs and roof at any one point along an entry is greater than necessary for the actual determination of its contents, the dust is screened, mixed and divided into four parts and from each division is taken a few ounces to comprise the sample proper which weighs about  $\frac{1}{2}$  lb.

Volumeter Chart

The volumeter does not give the percentage of rock dust direct but it can be determined by the use of this chart.

through a 200-mesh sieve and is dry must be classed as exceedingly flammable. If, however, these coal dusts do not contain more than 45 per cent combustible matter, they are not likely to cause an explosion unless there is also 1 per cent or more of methane present in the air.

An examination for the coal dust hazard, by a competent safety engineer,

must be made of each mine contemplating rock dusting. Samples must be taken of the coal at different points in the mine, and of dust from the roads, and from rib, roof and timber in the approved manner, and then sized and analyzed. Likewise, the quantity of dangerous road and rib, roof and timber dusts in a specific stretch of passageway must be calculated with a view to determining whether they should be cleaned before rock dust is applied, also the approximate quantity of rock dust by weight that will be required to rock dust properly a given length of passageway. All records should be kept accurately and systematically.

It may be stated that in examining the records of the sizing and analysis tests of a number of samples of dust collected in entries of dry and dusty mines in the Pittsburgh bed before rock dusting was started, the average incombustible content of the haulage road samples was 43.5 per cent, the range being between 27.2 and 54.6 per cent. The average incombustible content of the same number of rib, roof, and timber samples taken at the same points was 30.8 per cent, with a range of 20.7 and 50.1 per cent. It might be added that the quantity of 200-mesh dust contained in the road samples, all of which had passed a 20-mesh sieve, ranged from 17.4 to 27.0 per cent. The quantity of 200-mesh dust contained in the rib, roof, and timber samples, all of which passed a 20-mesh sieve, ranged from 54 to 65.3 per cent.

A rock dusting testing kit is now on the market, and has been designed to collect samples, to make size tests of coal dust and pulverized rock dust, and to make a rapid "volumeter test" for incombustible matter in coal and rock dust mixtures. For convenience, the outfit is assembled in two distinct parts, one the sampling kit and the other the equipment necessary for sizing and testing. This outfit, with a few modifications, is that developed by the Bureau of Mines and is described in Technical Paper 144, a revised edition of which was published in October, 1924. With a little study, any responsible man about a mine can use this kit with a proper degree of accuracy and efficiency. It might be added that for all practical purposes, the carbon dioxide and inherent ash and moisture which may be in any particular coal, can be ignored in preparing calibration curves.

Physiological tests have shown that pure limestone dust is not injurious to health. This material is now commonly used at mines, principally because no mining company knows much about the pulverizing business and all desired to make an early start in rock dusting their mines. At mines practising rock dusting it is

agreed that the most convenient dust to handle, and obviously the most effective, is that dust all of which will pass a 50-mesh sieve, and at least 60 to 70 per cent of which will pass 200-mesh.

Limestone dust can be purchased from many limestone companies, and is usually shipped in 80-lb. sacks, similar to flour and cement, which arrangement facilitates and prevents loss in handling. Sacked limestone dust of which 50 to 60 per cent will pass through 200-mesh, can be purchased at Youngstown, Ohio, for \$4.50 per ton, plus freight charges to the Pittsburgh district of \$1.50 per ton, or a total of \$6.00 per ton. Limestone dust of which 75 per cent will pass 200-mesh and prepared for shipment in the same manner, can be purchased in Bellefonte, Pa., for \$5 per ton. Transportation charges to the Pittsburgh district are \$1.50 per ton, or a total of \$6.50 per ton. Sacked limestone dust, from Erie, Pa., 60 per cent of which passes 200-mesh, can be delivered in the Pittsburgh district for \$5.90 per ton, and dust 80 per cent of which will pass 200-mesh, at \$6.45 per ton.

# Machine Cuts Power Costs And Saves Copper

By Bettering the Power Factor of Present Circuits  
Expensive Changes May Not Be Necessary

By a British Correspondent

**S**YNCHRONOUS motors have been used for years to correct the power factor of alternating-current circuits. Their application in mine installations, however, has been limited to continuous-running machinery such as ventilating fans, air compressors and motor-generator sets. In these capacities the synchronous motor forms a useful adjunct to the electrical installations of mines. The original type of machine, with its salient poles resembling, in its construction, an ordinary alternating-current generator, has inherent weaknesses which militate against its use except in places where technical supervision is available. The synchronous motor and equipment entail a high capital cost, and require synchronizing gear as well as the ordinary switching equipment. Originally it had to be

provided with an auxiliary motor, usually of the induction type and mounted on the same shaft, to bring it up as near as possible to synchronous speed, which could never be reached owing to the slip in the induction motor itself. A squirrel-cage damper winding is now employed for starting the more modern machines.

To synchronize effectually, the operative must be skilled, the operation often being attended with great difficulty, especially when the voltage and frequency of the power supply are unsteady, as indeed they often are where a fluctuating mine load is being carried by a comparatively small power plant. The difficulty is not entirely absent when power is supplied by a utility company which operates large generator units. However, the rapidly varying loads of the different consumers usually form a very small proportion of the total load carried by a large generating station and therefore do not so seriously influence either the voltage or frequency of the supply. Further disadvantages of the old-type synchronous motor are that any serious overload will cause it to fall out of step and come to a standstill, and that much time is lost when the processes of running up to speed and synchronizing have to be repeated.

These drawbacks of the synchronous motor have prevented many mines from adopting them even though they effect a large saving in line losses and also increase the power-carrying capacity of the power-distribution system. The effect of power factor on the current required for a given output on a three-phase system may readily be seen from the accompanying table which gives, for an output of 200 hp., the current necessary per line at power factors ranging from unity to 0.7 on a 400-volt circuit.

Current Needed with Varying Power Factor		
Horsepower	Power Factor	Amperes
200	1.00	215
200	0.95	227
200	0.90	239
200	0.85	253
200	0.80	269
200	0.75	287
200	0.70	308

It will be seen from these figures that a cable supplying 200 hp. at 0.7 power factor on a 400-volt circuit, has to carry about 43 per cent more current than it

Synchronous  
Motor with  
Rope Drive

Efficient slow-speed synchronous motors are now available for fan drives. When coupled to fans through speed-reducing devices a synchronous motor becomes a valuable asset to the mine property.

would if the power factor were unity. In that instance the raising of the power factor to unity would enable the same cable to carry more than 85 hp. of additional load at unity power factor. With old established plants contemplating extensions, power-factor improvement will often avert the heavy expense of scrapping existing cables and overhead lines for others of larger size. Therefore, should a suitable and cheap means of power-factor correction be available and one that does not entail the employment of expert operators, its advantages should appeal to the engineer of every mine alternating-current installation.

The asynchronous-synchronous type of motor combines in one machine the high starting torque common to the induction motor with the ability of the synchronous machine to operate at unity or even a leading power factor. Its construction is similar to the ordinary slip-ring induction motor, but the asynchronous-synchronous machine has four slip rings and has a small direct-coupled exciter. This type of motor, examples of which are shown in the accompanying illustrations, as manufactured by the English Electric Co., Ltd., of London, has the advantage over the salient-pole type of synchronous motor in that it has a high starting and synchronizing torque. Further, the salient-pole motor, as a rule, is synchronized when operating under reduced voltage, and this naturally increases the slip and reduces the power available during the synchronizing periods.

The efficiency of an asynchronous-synchronous motor of medium speed does not differ from that of the ordinary induction motor, yet it is from 0.5 per cent to 1 per cent higher at low speeds when built to operate at unity power factor. On the other hand, with a leading power-factor the efficiency is somewhat lower. The overload capacity of asynchronous-synchronous motors is roughly 70 per cent.

When being started the rotor is connected to an

ordinary type of liquid rheostat starter. After the motor is brought up to approximately full-load speed, by means of a double-throw switch the rotor leads are connected to an exciter. This affords additional torque which is alternately a motoring and a generating one as the rotor poles relatively slip backwards past the rotating stator field. The rotor increases in speed during the half cycle when the torque is motoring. Opposed to this increase in speed of course are the load torque on the motor and the inertia of the rotor and exciter to acceleration. Inversely proportional to the slip is the length of time during which acceleration takes place.

A useful feature of the asynchronous-synchronous motor is that it will synchronize without difficulty against a considerable overload. Moreover, when running in synchronism an excessive overload will have no more serious effect than to make the motor run as the ordinary induction type at a reduced speed. Immediately the overload is reduced to normal, the motor will again synchronize itself automatically.

As the asynchronous-synchronous motor runs at unity or leading power factor it may be employed to correct a low power-factor system, thus reducing the cost of feeder and substation extensions. If the asynchronous-synchronous motor does not have much lagging current of other power-consuming units to correct the design for unity power factor is the most suitable as it has greater efficiency and costs less than one rated for a leading power factor. For instance, a 500-hp. motor running at unity power factor on the same circuit as a similar machine operating at, say, 0.7 power factor will give a resultant of 0.9 for the total load of 1,000 hp. Everything considered, the asynchronous-synchronous motor is a desirable type of drive to install in suitable places about mines, for it combines in one machine the advantages of the induction and of the synchronous motor and thus corrects power factor.

**Complete Units Like These Frequently May Be Used To Better Voltage Conditions**

Air compressors, ventilating fans, pumps and motor-generator sets are specially suited to the use of synchronous motors. Heavy wattless currents flowing in conductors do no useful work, yet they necessitate oversized conductors and cause machines to heat unduly. The large quantity of power-factor corrective capacity is a synchronous motor while carrying a light mechanical load may often be used to advantage and save money.

# Ten Notable Points of Electrical Progress

Special Emphasis Laid on Emergency Provisions in Case of Power Failure—Gasoline Engines Though Less Economical Are Preferable to Oil Because of Lower First Cost

By GRAHAM BRIGHT  
Consulting Electrical Engineer,\*  
Pittsburgh, Pa.

**D**URING the past twenty years the use of electric power in and about coal-mining properties has so greatly increased that already most coal mines are using electric power exclusively, but a fair proportion in some parts of the country are still using steam for all or part of their power requirements.

It has been demonstrated that, where power can be purchased at a reasonable rate, an entirely electrified mine with purchased power is usually the most economical.

Among the recent developments toward the better and more economical use of electric power might be mentioned: (1) Long belt conveyor systems involving several miles of belt and requiring electrical equipment of the highest order to meet the exacting requirements of such a system; (2) the application of the synchronous motor to mine-fan drive, using new types of synchronous motors combined with internal and external clutches, operating either automatically or manually; (3) the application of the commutator type of alternating-current polyphase motor to mine-fan drives for variable speed operation; (4) the application of automatic substation and switching equipment to coal mine operation; (5) permissible locomotives and motors for safe application to gaseous mines; (6) new methods of bonding rails, including electric bonding machines; (7) magnetic and pneumatic types of control for locomotives and hoists; (8) small steam turbo-generators and the uni-flow engine for isolated plants; (9) development of high grade and reliable gears of spur, herringbone and worm type, enabling the use of high speed motors for hoist, fan, locomotive, pump, and conveyor drives; (10) emergency power units to supply power to keep up ventilation and remove men from a shaft mine in case of failure of purchased power.

A complete paper could be written on any one of the above subjects, but this paper will be confined to the last.

## LINE TROUBLE UNLIKELY

The service at a modern, up-to-date central-station power plant, will be, in general, more continuous than at an isolated plant. The transmission system of the central-station company may change this situation, for the power lines often pass over wild country and in most cases line trouble cannot be cleared up immediately. Where duplicate power lines from two different directions are available, a prolonged shutdown due to line trouble is little likely to occur.

In some cases steam plants are installed to obtain the highest percentage of continuity of service possible. This is generally a mistaken idea, as a serious shutdown is just as likely to occur with a steam engine as with an

electric motor. It has been found that where engines in coal mines have established a long record for continuity of operation, these engines are invariably greatly underloaded and consequently wasteful in the use of power.

The most important reason for providing emergency power is the safety it affords. It is usually applied in mines that are gaseous and where a shutdown of short duration may prove dangerous to men and property. This is particularly true in regard to gaseous shaft mines. Maximum safety is assured when emergency power is afforded to maintain the ventilation and remove the men from the mine in a short space of time.

## STEAM FOR EMERGENCIES

A number of mines, in changing from steam power to purchased electric power, have retained part or all of the steam plant for emergencies. This necessitates generating steam 24 hr. per day and also keeping the fan and hoisting engines in good condition. A mine thus equipped may not use the steam plant once a year, but the equipment should be tested frequently to be sure that it will be in operating condition when needed. The cost of maintaining such a system is unduly high.

A scheme now coming into common use is to install a gasoline- or oil-engine driven generator of about 100 kva. capacity. The generator is usually wound to suit the auxiliary hoist motor, which, in most cases, is a 2,200- or 440-volt, three-phase, 60-cycle wound rotor induction motor. The auxiliary hoist usually operates in the air shaft and in most cases hoists and lowers the men.

If the fan requires much power, and in a large gaseous mine, it usually does, there will not be sufficient power to operate both the hoist and the fan from the emergency plant, unless a two speed or variable speed fan motor is used, in which case the power required by the fan can be greatly lowered by reducing the fan speed.

As there is no particular object in obtaining economy in the operation of emergency equipment, a gasoline engine should be chosen rather than an oil engine. A high grade gasoline engine can be started in a minute or two with assurance, and because the period in which it is in operation is short, the fuel consumption is not an item to be considered.

A gasoline engine has been used to drive the fan direct, in case of emergency. This is accomplished by clutches. In most cases, however, the electric drive is simpler and more satisfactory.

There are many operations in the coal fields where there is no hoist in the auxiliary shaft and the men are hoisted and lowered in the main shaft. The main hoists of such mines usually have a capacity ranging from 300 to 600 hp.

The largest gasoline engine available has a capacity

NOTE—Article entitled "Recent Progress in Use of Electricity in Coal Mines," read at the Coal Mining Institute of America, Dec. 3-5 at its annual meeting held at Pittsburgh, Pa.

\*Howard N. Eavenson and Associates.

of about 300 hp. at 1,000 to 1,200 r.p.m. An engine of this type undoubtedly would be inadequate to supply power for the main hoist and the fan. The main hoist, however, usually operates at a speed considerably higher than that necessary and desirable for hoisting men. Furthermore, during the short period required to get the men out, it would be permissible to operate the fan at a reduced speed, provided it has not previously been stopped an appreciable length of time.

Manifestly, a scheme that would permit the hoist and fan to operate at reduced speeds without any loss of power other than the inherent machine losses, would permit the use of a moderate size gasoline-engine generator equipment. Such a scheme is available by the use of a reduced frequency and voltage. An induction motor will operate economically at a reduced frequency if the voltage is reduced in the same proportion. The speed also will be reduced proportionately. If the frequency is reduced 50 per cent the power and speed of the hoist motor will be reduced 50 per cent with the same load, and the power required by the fan motor with a 50 per cent speed reduction will be from one-quarter to one-fifth the full-speed power.

About a year ago, at one of the plants of the Youghiogeny & Ohio Coal Co., near Pittsburgh, a scheme involving the use of reduced frequency was installed for emergency service. At this plant are located two hoists, each being equipped with a wound-rotor induction motor of 400 hp. capacity and two fans each being equipped with a 150-hp. wound-rotor induction motor. The hoists and fans are within a few hundred feet of each other, and as the mines are gaseous it is extremely important that some ventilation be kept up while the men are being removed from the mine, in case of failure of power.

#### HOISTS OPERATED ALTERNATELY

A cage load of men weighs less than the usual load of coal and the maximum load during the hoisting cycle when hoisting men with power of one-half frequency is about 120 hp. The load on each fan motor at half frequency is about 35 hp. The hoists can easily be operated alternately by signal lights so that both are not taking power at the same time. Under these conditions the maximum load required is 190 hp. when one hoist and both fans are operating, and 70 hp. when only the fans are running.

The equipment selected to meet the above conditions consists of a 240-hp. high-grade Sterling gasoline engine of the Viking type, with dual ignition and dual starting equipment, direct connected to a 175-kva., 1,100-volt, three-phase, 30-cycle, 900-r.p.m., alternating-current generator. If necessary, this equipment could be operated at 40 cycles, in which case the engine would be operated at 1,200 r.p.m., and thus have a capacity of 320 hp. The generator would have a capacity of 233 kva. at about 1,475 volts.

To assure satisfactory operation a voltage regulator should be installed with outfits of this type. The equipment, referred to above, meets all the safety requirements, and can be placed in operation within one minute after failure of power. It is only necessary to press a starting button and operate a double-throw switch to substitute 1,100-volt, three-phase, 30-cycle power for 2,200-volt, three-phase power at 60 cycles.

Various combinations of generators can be used to

meet different conditions. Where pumping must be done it would be necessary to furnish full-frequency power for centrifugal-pump motors. This could be accomplished by an extra 60-cycle generator or a separate gasoline engine-driven generator.

Where a direct-current hoist is used with field control, a variable voltage direct-current generator could be used with the emergency set, and the speed of the hoist would depend upon the capacity of the gasoline engine.

An arrangement of a small steam turbo-generator receiving steam from one or more flash-type boilers may be feasible. Boilers of this type are used on steam automobiles and can be fired in a short time or kept under pressure automatically. The generator would be geared to the turbine and designed for full-frequency or reduced-frequency alternating current or direct-current, as conditions may require.

The advantage of the type of emergency equipment installed at the Youghiogeny & Ohio mine is that it is reliable and may often save the loss of a day's run, which, if repeated too often, will make it difficult to keep men. The equipment is not expensive, and therefore can be purchased by small as well as by large mines.

## Carnegie Institute to Train Graduates at Mines

Pittsburgh Mining Men Agree to Give Three Years Experience to Certain Number of Students Paying Them Salary the While

**A**N OPPORTUNITY will be afforded the student of bituminous coal mining to bridge the gap between the class room and the practice of mining, according to the announcement of Edward Steidle, supervisor of co-operative mining courses at the Carnegie Institute of Technology, Pittsburgh, Pa. This is the outcome of a report made by a special committee to the advisory board, Nov. 10 of this year, the chairman of the committee being J. M. Armstrong, general manager of the Pittsburgh Coal Co. The committee said:

"Business may owe the graduate nothing that it does not also owe to every young man, but it is good business to train promising young men in industrial methods and operations and this fact is demonstrated by the large number of corporations in nearly every branch of industry that offer training courses for college graduates. A college education should enable a young man to develop more rapidly than he would have done without the education, and the obtaining of such an education is to his advantage, because business will compensate him according to service rendered. The burden of delivery, however, is on the man.

#### COMMON SENSE BIG ASSET

"A college should teach a young man that his real training begins when he graduates; that in college his mind is trained only to a quicker comprehension of the problems with which he will meet in the course of his practical education; that his examination for entrance to the school of practical education will be at least as severe as his entrance examination to college; that while philanthropy may be business, business is not philanthropy, and that common sense will be one of his greatest assets; that if he is to succeed it will be neces-

sary for him in many instances to subordinate to practical considerations the theory that he has been taught.

"College graduates have been willing to go into a banking institution, start at the bottom and spend years in working up to the compensation equivalent to that of the inside laborer of a coal mine; into a mercantile establishment to become the head of a department; into a manufacturing establishment to get within sight of the headship of the department; but they have not been willing as a class to start at the bottom in the mining industry and stick until developed into men that any well directed company would feel justified in placing in control of its properties.

"If a college will encourage its mining graduates to follow coal mining, there will be no question that the mining industry will co-operate to such an extent that it will develop its entire official personnel from college-trained men."

The "Training Course in Bituminous Coal Mining for Technical Graduates," as it is to be termed, is designed to accommodate men of good physique and address having had a technical education either at the Carnegie Institute of Technology or elsewhere. The course will extend over two years, or twenty-four months, and will begin on or about July 1 of each year. A third year will be spent in specialized training. The student will not be bound by contract. While on the training course he will be considered as a student employee, not necessarily, however, as a coal loader or machine helper, but in all cases, unless otherwise warranted, he will work as a helper. In other words, at no time during the training course shall he be expected to be a total liability to the company.

Effort will be made to place him at a mine supervised by a fair-minded and helpful superintendent and mine foreman, but he may be moved from one mine to another as warranted. While at a union mine he will not be required to join the United Mine Workers of America. On completing the training course he will be interviewed by the general manager or general superintendent and may be assigned to a definite position during the third year, concentrating on the class of work in which he is most interested or for which he seems best fitted but involving some measure of respon-

sibility. At the end of the course of training, the company may rate and place the student or may drop him entirely. The student, in turn, may stay with the company or seek other employment.

#### SALARY TO BEGIN \$100 PER MONTH

At present the student will begin the course of training at a salary of \$100 a month, which will be increased \$10 at the end of each six months so that during the last six months he will receive \$130 a month. The pay during the third year will be the regular salary for the class of work performed. The employer is at liberty to drop the student at any time during the course if he shows a lack of interest in the work, does not perform it satisfactorily or does not mix well with the men.

Throughout the course of training the student will prepare comprehensive notes and follow as closely as practicable the headings and sub-headings indicated in the outline of training shown in the accompanying table. The officials of the Co-operative Mining Courses of the Carnegie Institute of Technology will keep in close contact with the student as approved by the mining company concerned. The College of Engineering will recommend for the degree of Engineer of Mines any student who has successfully completed the course of training and presented a satisfactory thesis on some phase of coal mining, provided further that he has had two years in responsible charge of work.

At present the State Department of Mines requires that applicants for the positions of mine foreman and fireboss must have had five years' experience in the bituminous mines of Pennsylvania. It is believed that this law will be revised, thus giving technical graduates in mining credit for two years of practical experience. This change in the law would allow students completing the training course to qualify for the state examinations for these certified positions.

At the end of the training course, the company will grade each student on the following points: Common sense, energy, initiative, leadership, reliability and general ability. If he has done satisfactory work, the company will give him an executive or operating position in the work for which he seems best suited.

### Outline of Training Course, Carnegie Institute of Technology

#### Subjects to Be Studied

<b>Trackwork</b> (Materials, tools and labor necessary to accomplish certain results, bonding, grading, costs).....	1 month
<b>Timbering</b> (Materials, methods of placement, quantity and labor needed, costs).....	1 month
<b>Wiring</b> (Equipment, size of wire needed, hangers and insulators, switches for all conditions, placing of switches, guarding, costs).....	1 month
<b>Drainage</b> (Elevations in mine and on surface, water centralization, pumping equipment, laying and connecting of pipe, guarding, costs).....	1 month
<b>Ventilation</b> (Volume needed, ventilating equipment, air-courses, stoppings, splitting of air currents, regulators bratticing, materials and tools necessary, costs).....	1 1/2 months
<b>Hoisting</b> (Hoisting plant, conveyors, operation, inspection and repair, costs).....	1 month
<b>Haulage</b> (Gradients, condition of tracks, condition of trolley wire and bonding, locomotives and their operation, mule and rope haulage, mine wagons, distribution of haulage partings, gathering in all its phases).....	1 1/2 months
<b>Shooting Coal and Rock</b> (Preparation of face, placing of holes, types of explosive, placing of explosives, tamping and material for same, precautions necessary).....	1 month
<b>Mining</b> (Nature of coal being worked, top to be cared for, development methods, undercutting in advance and retreat, roof control, recovery of timber, modified methods, care of abandoned workings, costs).....	2 1/2 months
<b>Coal Preparation</b> (Tippie design, sizing of coal, cleaning, weighing, trimming, costs).....	1 month
<b>Supplies</b> (Quality and quantity, receipt and distribution, records, costs).....	1 month
<b>Power and Substations, Surface and Underground</b> (Machine types, housing, lubrication, safeguarding, repairs, costs).....	2 months
<b>Clerical</b> (Timekeeping, payrolls, records including costs, house rents, coal sales and reports to general office).....	2 months
<b>Shop</b> (Work on all classes of electrical and mechanical appliances, pumping equipment and sufficient time in stock room to become familiarized with different classes of stock, costs).....	2 months
<b>Supervision and Inspection</b> (Superintendent, mine foreman, assistant mine foreman, fire boss, company inspector, costs).....	1 1/2 months
<b>Personnel Work</b> (Medical insurance, welfare, costs).....	1 month
<b>Engineering Corps</b> (Surveying, construction, drafting, costs).....	2 months
<b>Reports in Engineering Department</b> (Detailed investigation, valuation, surface and underground layouts).....	1 1/2 months
<b>Total</b> .....	24 months

## Hail to the New World's Record Coal Mine!

Valier Mine in Southern Illinois Establishes New Mark

By Hoisting 8,664 Tons in One Day

ON NOV. 25, another world's record was established. On that date the Valier Coal Co.'s mine at Valier, in southern Illinois, in 8 hr. hoisted more coal than any one shaft, so far as is known, ever produced before in the history of coal mining—8,664 tons. This exceeds by 446 tons the greatest day's hoist previously produced—the record of 8,218 tons established some time ago by the Orient No. 1 mine of the Chicago, Wilmington & Franklin Coal Co., at West Frankfort, Ill. Another of the “whopper” southern Illinois mines—Zeigler No. 1 of the Bell & Zoller Coal Co.—in October made the largest month's hoist in history—189,240 tons. Thus the record-breaking habit is strong in this region.

The Valier mine, owned and operated through a subsidiary by the Burlington railway, has long been recognized as a good 6,000-tonner but nobody expected it to break a world's production record. Changes in management and methods during the past year have increased the capacity of the plant without the installation of much additional equipment. Thus the great day's run of Nov. 25 was made possible without previous notice.

### MADE OVER TWO THOUSAND DUMPS

In the eight hours of hoisting on that day, the time lost totaled nine minutes. Two minutes were required for cleaning the sump, three were lost by a car getting stuck in the dump, power was off for one minute and three more minutes were consumed rerailling a load on the bottom. A total of 2,036 dumps was made which gives an average load of approximately 4.3 tons per car throughout the day. Only 600 cars were in coal service on the day in question so that they averaged about 3.5 round trips each, an unusual performance.

Naturally the neighbors wondered what made it possible for Valier to make such a huge run, and searched for causes. The best reasons they could find were as follows: On Nov. 24, the day previous, the dump broke at 12:40 p.m. The underground workings continued to produce coal for 2 hr., 10 min., or until 3 p.m. when the mine blew “all over” for the day and the last man came out. Of course some coal was produced and placed on wheels for the next day during this 2 hr. 10 min.

However, the critics certainly would agree that there would be nothing left over after the tremendous run of the 25th, yet on the 26th the mine produced 7,681 tons without half trying and with absolutely no preparation. This gives much justification to the claim that the mine has the “greatest” tonnage ever hoisted from a single shaft.

### TONNAGE EXCEEDS ESTIMATE

In the June 24, 1920 issue of *Coal Age*, Carl Scholz, who opened the property and designed the equipment, stated that the main shaft was planned to produce 6,500 tons daily. It is clear that it has a much larger capacity. For reaching the large tonnage the leisurely method of the two-car rotary dump and skip are used. Without unusual hustle such equipment makes possible a large tonnage. The skip has a capacity of 15 tons and the guides are of 85-lb. track rails.

The hoist is arranged for automatic acceleration, automatic slow-down and stop. It is necessary only for the operator to close the control switch in order to start the hoisting cycle. A pilot motor then turns the controller to the full-speed position, whereupon this motor is cut off and unclutched. Near the end of the travel of the hoist, cams turn the controller to the off-position and when this is reached the brakes are automatically applied.

One of the factors that permitted the large output to be made, doubtless is to be found in the large cars. Originally designed to hold 5½ tons they were, as stated earlier in this article, hauling only 4.3 tons, but even that is a tonnage per car that gives large economies in operation. Though shaft sinking was started in September, 1917, and coal was reached in May, 1918, and despite the fact that the Valier mine made remarkable advances in tonnage, it has taken over seven years to reach this preeminence. This is a clear indication of the long period between the inception of a coal project and the attainment of maximum output.

W. M. Dickson, purchasing agent for the Valier Coal Co., is acting general manager. F. F. Green is superintendent. D. W. Jones is electrical engineer and Charles E. Anderson underground manager.

# Live Topics Elicit Animated Discussion at Meeting of West Virginia Coal Mining Institute

Rock Dusting, Pneumatic Separation of Coal and Electrification of Gaseous Mines by Storage Batteries Hold Interest at Winter Session—Lambie is New President—First-Aid Meet Well Managed

By J. H. EDWARDS  
Associate Editor, *Coal Age*  
Huntington, W. Va.

**R**OCK DUSTING, pneumatic separation of coal and electrification of gaseous mines by storage batteries, were the subjects dealt with at the winter meeting of the West Virginia Coal Mining Institute held at Welch, W. Va., Dec. 2 and 3. This meeting, quoting Frank Haas, consulting engineer, Consolidation Coal Co., "was one of the most successful in the history of the institute." The first morning session was attended by more than seventy-five men, this, according to Joseph Reed, retiring president of the institute, being almost a record attendance at an early morning session on the first day.

William J. O'Toole, general manager of the American Coal Cleaning Corporation, read a paper on pneumatic coal separation. He reviewed the progress of the dry-cleaning process to its present stage of development, citing a number of first class installations now in operation. He declared that treatment by air is yet in its infancy, but that water cleaning has already been perfected to a point where inherent characteristics limit further important development.

In his paper Mr. O'Toole stated that the use of rotary screens instead of other types would reduce the operating cost of the extensive sizing which is required for pneumatic separation. He also emphasized the point that the substitution of air cleaning for washing would eliminate the pollution of streams which is now becoming a serious problem.

He described the problem of handling the dust encountered with the first installations. A material increase in the volume of air drawn from above the table and into the dust collecting system has solved this difficulty. The ordinary cyclone collector system is satisfactory except in cities having strict anti-smoke ordinances, in which cases the bag type of collector must be used.

## DUST COLLECTOR LESSENS FIRE HAZARD

Answering a question, R. M. Lambie, chief of the West Virginia Department of Mines, said, in substance, that at a plant which is equipped with the latest type of cyclone dust collector there is no longer any fire hazard from dust floating about in the building.

Thomas Fear, general superintendent, Inland Collieries Co., Indianola, Pa., suggested the possibility of reducing the quantity of dust by treating the coal with oil or in some other manner before it goes to the air cleaner, or possibly before being dumped.

Questions were asked Mr. O'Toole regarding the commercial value of the dust. He stated that some dust had been sold at \$15 per ton for foundry facings. He added, however, that this market is limited. He also said that for some unexplained reason the dust runs higher in ash than the coal as received.

Mr. Fear read a paper describing rock dusting experience at the Indianola mine. Last February, sprinkling, for which approximately 20 miles of pipe was used, was abandoned in favor of rock dusting. There is now 58 miles of dusting in the Indianola mine. The present practice is to redust whenever an analysis of road dust samples indicates below 55 per cent of combustible content.

During May this mine used 2 to 3 lb. of limestone dust per lineal foot of entry, and the cost of dusting was 1.1c. per lineal foot. During the last six months the company's records show an average of 4,000 ft. of entry dusted in eight hours, at a cost of \$40.60. The experience to date indicates that if entries are dusted twice a year it will cost 2 mills per ton, and if dusted four times per year, 4 mills per ton.

A recent analysis disclosed that about 50 per cent of the rock dust applied last spring and which during the summer had become caked by moisture, had returned to such a condition that it would be thrown into suspension in case of a violent disturbance.

Mr. Fear's paper was followed by a lively discussion which brought about a comparison of conditions at Indianola and what might be encountered in a seam such as the Pocahontas No. 3. Mr. Lambie stated that in West Virginia no credit on compensation is allowed for rock dusting. Mr. Fear said that in Pennsylvania 10c. is allowed per \$100 of payroll.

## MAIN HAULWAYS DUSTED TWICE A YEAR

Mr. O'Toole asked how often per year the entries at Indianola must be dusted. Mr. Fear replied that present experience indicates that the main haulways must be dusted twice a year. About 300 tons of rock dust has been put into the Indianola mine this year.

Mr. Crawford, of the Mine Extension Department, University of West Virginia, inquired about the loading of machine cuttings into the bottom of the car, before shooting. Mr. Fear stated that this practice has been abandoned, the coal now being shot down on top of the dust. Replying to a query on how close rock dusting is kept to the face, Mr. Fear explained that entries are kept dusted to the last cross-cut, which ordinarily means a maximum of 80 ft. left undusted.

The possible difficulties of effective rock dusting in seams such as the Pocahontas No. 3, as compared to the Pittsburgh seam, which is mined at Indianola, were discussed by Mr. Lambie. The higher percentage of fines and lower height of entries were mentioned as possible difficulties. Mr. Fear stated that after a recent trip through a Pocahontas No. 3 mine he concluded that there is no more dust being deposited than at the Indianola mine. He also stated that low height with attendant greater air velocities would have little

effect in dislodging the rock dust from ribs and roof. He said that it is only the first trip passing through a newly dusted entry which dislodges any appreciable quantity of the dust. The second trip brings down very little.

At Indianola, washing down the ribs with water before rock dusting is not done, as rock dusting is not so effective if the ribs are slightly wet. Furthermore, it has been found that the blast of rock dust when being applied actually washes down to the floor a large percentage of the coal dust.

In his paper Mr. Fear described the advantages of rock dust stemming and he indicated this practice is being followed at Indianola. He cited as advantages, greater safety, a saving of 20 to 30 per cent in the quantity of explosive and an increase of 9 to 20 per cent in the quantity of lump coal.

Following Mr. Fear's paper, John T. Ryan, Mine Safety Appliance Co., Pittsburgh, Pa., gave an illustrated talk on sampling—and analyzed mine road dust and exhibited and demonstrated a compact commercial outfit for determining the non-combustible content by the specific gravity method. This method of analysis is correct to within about 5 per cent, the greatest error being introduced by the varying moisture in the sample. A correction can be made, however, if the quantity of moisture in the sample is known.

It was recommended that of the samples collected only that portion passing through a 10-mesh screen be brought out for analysis, and that this be further reduced by a 20-mesh screen before making the specific gravity test. Mr. Ryan stated that in France the regulations require that mine dust samples show 70 per cent of non-combustible before being considered entirely safe.

In answer to a defense of sprinkling Mr. Ryan stated that it requires at least 30 per cent of moisture in coal dust to insure any degree of safety, but that such a content does not remain fixed any definite length of time. A rock dust content, on the other hand, undergoes much slower changes.

#### ELECTRIFICATION GROWTH DESCRIBED

The paper read by John B. Hicks, of the Consolidation Coal Co., Fairmont, W. Va., on electrification of gaseous mines by storage batteries, described a new departure in methods of utilizing electricity with greater safety for coal cutting and handling. Developments in design of straight storage battery locomotives with safe electrical equipment, for gathering and handling, were described. The power truck or, in other words, the self-propelled portable storage battery for furnishing power to a mining machine, is a departure which, perhaps, no company besides the Consolidation has tried.

Experience with a number of these power truck outfits has demonstrated their practicability for gassy mines, indicating that their adoption in any mine may be considered from the standpoint of economy alone.

In the discussion Mr. Knight asked how teetering is avoided in the main haulage battery locomotive which was described in the paper as being 19 ft. long and having a 70-inch wheelbase. Mr. Hicks explained that the battery compartment is adjustable so as to obtain good balance and that the use of a long journal box with coil springs located about 12 in. apart also aids in overcoming any tendency the locomotive might have to teeter.

At the business meeting of the institute the following

officers were elected: President, R. M. Lambie, chief of the West Virginia Department of Mines, Charleston, W. Va.; first vice-president, T. M. Downing, Jr., general manager Logan Coal Corporation, Lundale, W. Va.; second vice-president, George Wolfe, secretary Winding Gulf Coal Operators Association; third vice-president, C. C. Morfit, secretary Tug River Coal Operators Association; fourth vice-president, E. S. Wade, West Penn Power Co., Beech Bottom, W. Va.; fifth vice-president, J. E. Lawall, head of mine extension department, University of West Virginia, Morgantown.

Executive committee—Frank Haas, consulting engineer, Consolidation Coal Co., Fairmont, W. Va.; W. E. E. Koepler, secretary Pocahontas Coal Operators Association, Bluefield, W. Va.; F. F. Carson, consulting mining engineer, Crane & Cole Co., Huntington, W. Va., and W. E. Fohl, consulting mining engineer, Pittsburgh, Pa.

The new president, Mr. Lambie, presided at a banquet of members which was held in the evening. Jack Morris, general manager of the MacBeth Coal Co., Logan County, and Thomas Stockdale, inspector of District 17, furnished vocal and instrumental entertainment.

#### REAPING THE UNDERGROUND HARVEST

The second day of the meeting was taken up by an automobile trip to nearby mines and by a first-aid contest. The first stop of the trip was at Gary No. 6 mine, where the visitors saw in operation the coal cutting and loading machine of Col. Edward O'Toole. This machine with its 43-ft. cutter bar, reminds one of the method used in the great wheat growing belts for harvesting grain. Like the large grain heading machines, it cuts a wide swath through the field, catches the material on a platform and elevates it into cars.

The party also visited the Gary power plant, where they saw two 750-hp. boilers being fired with powdered bone coal. Each furnace has five feeders, these blowing in and releasing the powdered fuel at a point 28 ft. from the floor of the combustion chamber. The bone coal is shipped in railroad cars to the power plant from nearby mines of the United States Coal & Coke Co.

From Gary the institute members were taken to Coalwood, where they were the guests of the Consolidation Coal Co. at a luncheon served at the club house. F. K. Day, general superintendent at Coalwood, was introduced as the man responsible for this wonderfully satisfying part of the day's program.

In connection with the institute meeting the McDowell County first-aid contest was held under the auspices of the Tug River and Pocahontas Coal Operators Association, the U. S. Bureau of Mines and the National Safety Council. Seventeen teams competed and, thanks to C. C. Morfit, who supervised the meet, there was no evidence of the confusion and long delays which are so often noticed at first aid contests.

The winning team from Exeter shaft of the Kingston-Pocahontas company, and captained by C. R. Angove, received a large silver trophy. According to the judges' score, two teams tied for second place, these being the team of the American Coal Co., McComas, captained by John W. Smith, and the team of the Lake Superior Coal Co., Superior, captained by Ray Ingole. The toss of a coin gave second place to the American company team, each individual member receiving as second prize a five dollar gold piece. A medal was given by the National Safety Council to each member of the three teams mentioned above.

## Jacksonville Agreement Fails to Cure Ills of Coal Industry

Forty-three per Cent of Country's Mines Shut Tight—Puts Wagon Mines Off the Map—Competitive Situation Unchanged—  
Legislation Impends in Congress

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Eight of the thirty-six months which constitute the life of the Jacksonville agreement have passed. It has been in effect long enough, however, to produce some extraordinary and far-reaching results, and the leaven has only begun to work. It has shut down absolutely 43 per cent of the mines. Without question it has concentrated coal production at the low cost properties, but it has only accentuated the cutthroat competitive situation between the union and the non-union fields.

When the Jacksonville agreement was signed the general feeling was that coal would cease to be a public issue for the three years it would run. The developments of the presidential campaign led many to believe that the coal industry would be allowed to work out all phases of its own salvation without being trammelled by the public or any of its official representatives. In the meantime, however, Congress has assembled. Bills are to be introduced in each house of Congress, it is understood, which will have a bearing on the coal industry. They may not propose regulation, but they will remind the industry that legislators are going to continue to suggest means which they think will bring about better functioning of an industry on which the whole public welfare rests. Certain plans, not yet ready for announcement, are being formulated in the executive departments.

### Public Opinion in Evidence

Striking evidence that the pressure of public opinion is behind these moves is had in the recent address of F. R. Low, retiring president of the American Society of Mechanical Engineers, who expressed satisfaction that the people's interest in power from hydro sources is protected by the federal water power act, but who brought out as one of the principal points of the message he left with his fellow engineers and with the country, that "an uninterrupted and abundant supply of power cannot be assured to the nation at reasonable rates so long as the fuel from which most of it is made is subjected to the uncontrolled manipulation of private interest and the organized

will—or won't—of labor." He cited as the "one crumb of comfort" in the report of the Harding Coal Commission its declaration that the mining and distribution of coal are charged with public interest.

The Jacksonville agreement was expected to freeze out the high cost mines. That it has done with a vengeance. No wagon mine has operated for over a year. Even among the more pretentious mines a large number are idle. A recent report to the U. S. Geological Survey shows that of 2,389 mines reporting 1,032 had been closed down. More than a thousand well equipped coal mines were not adding a ton to the country's production or contributing to any payroll. On the other hand, there were 295 mines which operated full time and 350 more that operated five days but less than six. The first part of the story is that the agreement has closed 43 per cent of the commercial mines and the business they formerly had has gone to some 25 per cent of the mines remaining, those better situated as to costs or markets.

### Finish of Many Mines Seen

It remains to be seen whether the 43 per cent will stay closed. They will hang over the market until their equipment is scrapped. The probabilities are that most of them cannot stand three years of starvation.

The second part of the story, however, is different. There has been no alteration in the competitive situation between the North and the South, between the union operators with rigid wage scales and the non-union operators with flexible wage scales. The Jacksonville agreement simply has made the inequalities of the competitive struggle even more cruelly apparent. The business not only has been shifted from small to large mines but it has moved in millions of tons from union to non-union districts. Before the Jacksonville agreement can be said to have settled the coal problem it will have to provide for this second aspect.

One of the results predicted was a reduction in the union scale. That is very likely to come, but it does not

### Talk of Queer Bedfellows!

To the miners' union the name "chamber of commerce" is as the scarlet to the bull. The International constitution of the union even specifies that union miners will have nothing whatever to do with a chamber of commerce. Yet what do we see out in Missouri? The miners' union of District 25 is trying its best to get the chambers of commerce of Missouri to co-operate in a "burn Missouri coal" movement and to enlist the chambers in a battle to give Missouri coal a more favorable freight rate in intrastate traffic.

constitute a permanent solution. It simply reduces the level below which the non-union operators must keep their wages in order to live. Even with union wages pegged where they are this has not been a profitable year for the non-union operators. They have shipped a large amount of coal, but few of them are doing more than breaking even. If union wages are reduced the pay at non-union mines will be reduced still more.

A result predicted by some is the distintegration of the union. It has been forced already to retreat from southern West Virginia and eastern Kentucky. Its hold on northern West Virginia, central Pennsylvania and the Southwest has been loosened. But even were the union to be broken up it would not constitute a permanent solution. Non-union territory simply would be swelled to larger proportions and even a more intensive competitive struggle would occur between non-union operators themselves. The more the union shrinks the more the non-union districts will find themselves in the condition that the whole country experienced during the nineties, when there was no agreement on wage rates and every man's hand was raised against his neighbor. The Jacksonville agreement has yet to demonstrate that it can settle the ills arising from union and non-union competition.

The feeling on Capitol Hill has not crystallized, but it is apparent that the legislators sense that the public has not forgotten its interest in coal. They also sense a very general feeling that the coal industry is not in an entirely healthy state. With the ever present desire on the part of the legislator to be doing something with matters which affect a large percentage of the people, there is no guarantee, even at this short session, against some agitation of coal legislation.

## Mine Accidents Claim 154 Lives in October; 10 Months Total 1,979

Accidents at coal mines in the United States during October, 1924, caused the death of 154 employees, according to reports received from state mine inspectors by the U. S. Bureau of Mines. The production of coal for the month was 54,487,000 tons; hence the fatality rate was 2.83 per million tons, as compared with 3.83 in the previous month and 3.11 for October last year. At bituminous mines throughout the country 123 men were killed and the fatality rate was 2.63 per million tons, as against 2.85 in October, 1923. At anthracite mines in Pennsylvania the number of fatalities was 31, indicating a fatality rate of 4.04, as compared with 4.59 for the same month last year.

The accident record for the year 1924 to Oct. 31 shows a total of 1,979 accidental deaths at the mines. Based on an output of 458,512,000 tons during the 10-month period, the fatality rate was 4.32 per million tons as compared with 3.91 for the corresponding months last year. For bituminous mines alone the 1924 rate for the ten months was 4.14 as compared with 3.63, while for anthracite mines alone it was 5.22 as compared with 5.56. The increase in the fatality rate for bituminous mines in 1924 was due to the larger number of deaths from explosions of gas and coal dust.

As no single accident in October killed as many as five men, the record of "major" disasters during the first ten months of 1924 shows 9 disasters with a loss of 452 lives as compared

## Miner Loses Two Thumbs From One Hand; Seeks Double Compensation

Born with two thumbs on the right hand, and losing them recently in a mine accident in the anthracite district of Pennsylvania, Anthony Cusatt, a miner, in a letter to the office of District 7 of the United Mine Workers, at Hazleton, last week, asked that he receive the backing of that body in an action for double compensation.

Cusatt wrote that the company employing him, the name of which he failed to give, had offered compensation for only one thumb at the rate of \$12 a week for sixty weeks. It is the most unusual case that has come to the attention of union officials, said John Yourishin, district secretary-treasurer, who looks after compensation claims of the miners.

with 8 similar accidents and a loss of 260 lives during the same months last year. The fatality rate based exclusively on major disasters stands at 0.99 per million tons for 1924 and 0.48 for the first ten months of 1923.

Explosions of gas and coal dust are the only class of accidents with increased fatality rates for 1924; for this group the fatality rate increased from 0.60 per million tons for January-October, 1923, to 1.13 per million tons in 1924.

## P. & W. V. Segregation Plan Approved by Stockholders

Pittsburgh & West Virginia Ry. stockholders have approved the proposal of the directors for the segregation of the Pittsburgh Terminal Coal Co. from the railway company. The proposed increase in the funded debt to \$3,000,000 by the issuance of equipment trust certificates also was approved.

F. E. Taplin, chairman of the board, said Dec. 2 that the segregation of the coal property and the retirement of the preferred stock would not be interfered with by any action on the part of the Interstate Commerce Commission regarding the proposed issue of equipment trust certificates. In an informal report on the application for authority to issue the certificates an examiner for the commission recommended that it be disallowed. Mr. Taplin said that even if the commission should uphold this report the Pittsburgh & West Virginia would adhere to its plan for the retirement of the preferred stock on the date designated.

The Department of State and Finance at Harrisburg, Pa., has approved the merging of the Pittsburgh Terminal Coal Co. and the Meadow Lands Coal Co., the name of the former being used. The capital stock of the company is \$17,200,000. The officers of the merged company are: C. E. Tuttle, New York, president; L. H. Kelly and G. F. Osley, Pittsburgh, vice-presidents; A. J. Appel, Pittsburgh, secretary, and E. C. McKibben, Pittsburgh, treasurer.

## Coal-Mine Fatalities During October, 1924, by Causes and States

## Budget Allowance Lower For Bureau of Mines And Geological Survey

The President and the Director of the Budget have approved proposed appropriations for the next fiscal year of \$1,876,560 for the Bureau of Mines and \$1,654,595 for the Geological Survey. These amounts compare with \$1,900,468 and \$1,706,482, respectively, appropriated for the work of the current fiscal year. If Congress insists on paring the budget in the same proportion as has been its custom, it will mean heavy curtailment of the work done by these two agencies. It is believed, however, that Congress will take into account the fact that drastic reductions have been made in the amounts originally requested by the heads of the separate executive agencies, and the prospects favor the actual appropriation of approximately the amounts carried in the budget.

Among the items making up the Bureau of Mines budget are investigating mine accidents, \$400,000; general expense, \$86,000; mining investigations in Alaska, \$33,000; operating mine rescue cars and stations, \$281,840; testing fuel, \$155,000; oil, gas and oil shale investigations and leasing work, \$456,000; enforcement of mineral leases, \$86,920; mining experiment stations, \$200,000; care of buildings and grounds at Pittsburgh, \$65,000.

Items making up the Geological Survey budget are preparation of reports on the mineral resources of the United States, \$123,000; geologic maps, \$105,000; examination and classification of lands, \$265,695; gaging streams, \$165,000; investigations of the mineral resources of Alaska, \$72,000; chemical and physical research relating to geology, \$40,000; geologic surveys in various portions of the United States, \$326,140; topographic surveys, \$485,000; Director's office, \$54,760; preparation of illustrations, \$18,000.

## \$5,000,000 Company Formed In Central Pennsylvania

With the organization of the Madill Coal & Coke Co., at Indiana, Indiana County, with a capital stock of \$5,000,000, one of the largest deals in recent years in the coal industry in central Pennsylvania has been brought about. The active head in the movement is John Madill, of Indiana. The project is backed by Pittsburgh, Buffalo and Eastern interests.

The corporation has taken over large coal acreages in Indiana and Cambria Counties, where plans have been matured to open mines, build a railroad, erect a town and otherwise complete what will become one of the largest operations in the district.

Plans have been completed for the construction of a railroad connecting the mines of the company with the Buffalo, Rochester & Pittsburgh, the Pennsylvania R.R. and the Cambria & Indiana Ry. This road will give access to the Buffalo and Canadian markets, as well as facilitate shipments to the East and tidewater. The road also will connect with Johnstown and the Bethlehem Steel Works there.

**James Elwood Jones**

Vice-president, Pocahontas Operators' Association but better known as the developer of the celebrated Coloder machine at the mines of the Pocahontas Fuel Co. The loader fills 370 tons of coal daily in actual everyday operation.

## Hard Coal Regions Want Part Of Tax for Local Use

*Special to Coal Age*

Scranton, Pa., Dec. 8.—Indications point to a concerted move by members of the Legislature from the anthracite region to bring about a return of about 50 per cent of the money collected by the state under the present anthracite tonnage tax to the communities and cities in which hard coal is mined. The anthracite tax is collected on a basis of 1½ per cent of the market value of all coal produced and sold.

The move to obtain a portion of the tax for the direct use of the citizens residing in anthracite communities has been launched by the Scranton Chamber of Commerce. The organization is enlisting the support of various municipal bodies throughout the anthracite region in the project.

The fight will not be a new one in the state Legislature. In the 1923 session a similar bill was passed, but vetoed by Governor Gifford Pinchot. In vetoing the measure the Governor declared that the state needed every cent of revenue it could lay its hands on to "clean up the mess."

With this session of the Legislature improved state financial conditions will be used as a further argument toward the passing of the bill providing for a return of part of the tonnage tax. An anthracite bloc of legislators will be organized and, it is believed, will push the measure through.

## New Haven Seeks New Bids

Announcement has been made that the bids received on Nov. 17 by the New York, New Haven & Hartford R.R. Co. for furnishing and delivering alongside, Boston, 400,000 gross tons of high volatile run of mine coal have been rejected and that new bids will be received up to Dec. 15 for between 360,000 and 410,000 net tons of the same quality of coal. This contract will run for one year from May 1 of next year.

## Union Affairs in Muddle In Hard Coal Region as Result of Outlaw Strike

*Special to Coal Age*

Scranton, Pa., Dec. 8.—The outlaw strike of 12,000 Pennsylvania & Hillside Coal & Iron Co. mine workers in the Pittston anthracite field has developed many complicating angles. It has created a furor in district union circles that may end disastrously for the present executives of the district. When the strikers refused to return to work upon the demand of John L. Lewis, president of the international union, the charters of the local unions disobeying the order were revoked and as a result 12,000 former United Mine Workers are now non-union men.

As the international union did not want to lose these men, however, President Lewis has sent a commission of five International executive board members into the Scranton district for the purpose of counselling the men to return to work and restore peace and harmony in the district, intimating that "if they fall in line" their charters will be returned. The commission met with the general committee of the strikers, but was unable to console the men to the circumstances and as a result the strike is still on.

A new phase of the situation has assumed magnified proportions. It is in the form of a call for a special convention of all local unions of district 1, demanded by the strikers and indorsed by the general grievance committees of the Hudson Coal Co., the Glen Alden Coal Co., the Lehigh Valley Coal Co. and the Lehigh & Wilkes-Barre Coal Co., representing over 50,000 mine workers of the district. A formal petition for the convention will be filed with the executive board of the district within the next few days. It is expected that the majority members of the board will refuse the demand. An appeal may then be made to the international union board. The purpose of the convention is expressed by the strike leaders as an effort to "investigate the muddled conditions of the district and place responsibility for the improper handling of grievances."

Neal J. Ferry, of McAdoo, Pa., is chairman of the special international union commission sent here by president Lewis. Other members are Ed Dobbins, of Belleville, Ill.; John M. O'Leary, of Pittsburgh, Pa.; John Mates, of Williamstown, Pa., and John Ghizzoni, of Homer City, Pa. They will stay in the district, they say, until the situation is adjusted.

## Anthracite Circular Prices For December

## W. A. Phillips, Well Known W. Va. Operator, Dies

W. A. Phillips, president of the Pemberton Coal & Coke Co., Affinity, W. Va., died Dec. 3 at the Lankenau Hospital, Philadelphia, where he had been for several weeks taking treatment for stomach trouble. Many years ago he started in the coal mines of the anthracite fields in an humble way. Realizing the possibilities of smokeless coal he and others from Schuylkill County, Pa., migrated to the Pocahontas fields of West Virginia, where they acquired valuable property. Later he went to the New River field, where he organized the Pemberton Coal & Coke Co. and acquired some valuable land in the Winding Gulf field. In this field he developed three mines, the companies which developed and operated them still owning and operating the same properties. Mr. Phillips also was president of the Ashland Coal & Coke Co., located in the Pocahontas field, and the Majestic Colliery Co., in the Williamson field. He also was extensively interested in the banking business at Mount Carmel.

Mr. Phillips was 84 years old. Funeral services were held at his late home, at Mount Carmel, Pa., Saturday afternoon, interment being at Fountain Springs Cemetery, Ashland, Pa.

## Reverses \$18,000 Judgment For L. & N. Against Nield

Judgment obtained last year in the Jefferson Circuit Court by the Louisville & Nashville R.R. against C. S. Nield, of Kettle Island, Bell County, Ky., was reversed, with directions that the petition be dismissed in an opinion delivered Nov. 21 by Judge E. S. Clarke, of the Kentucky Court of Appeals. The judgment, obtained in Judge Davis Edwards' court at Louisville, was for

## Lists Efficiency Experts Among National Wastes

National extravagance is the greatest danger to American prosperity, Robert E. M. Cowie, president of the American Railway Express Co., stated in an address before the Canadian Club of New York at the weekly luncheon at the Belmont Hotel, in New York, last week. Mr. Cowie attacked waste, the craze for efficiency agents and purchase on time payments as cardinal weaknesses, and described this country as "the most profligate of nations in the matter of waste and extravagance in business affairs."

The speaker, while admitting a greater need for efficient management in business, said that the idea of calling in outside assistance to create an efficient condition had been overdone.

\$18,000, representing a claim for \$11,000 and interest for ten years.

The L. & N. in its action sought to require Mr. Nield to pay for construction of 2,000 ft. of branch railroad track in Bell County, that being part of a branch from Pineville to coal properties in Kettle Island Creek. The appellate decision set forth that the railroad had not established a claim against Mr. Nield.

The branch was constructed in 1909 and 1910 at the instance of the Edgemont Coal Co., of which Mr. Nield was a stockholder. The other stockholders in the coal company resided in Atlanta, Ga. When the coal company planned to develop its property in Bell County, at the mouth of Kettle Creek, the L. & N. agreed to construct the necessary branch road.

## Constitutionality of Tax On Anthracite Upheld By U. S. Supreme Court

The U. S. Supreme Court on Dec. 8, without a written opinion, affirmed the decision of the lower court upholding the constitutionality of the Pennsylvania anthracite tax. An appeal was made by the Cranberry Coal Co. and others.

At the conclusion of arguments by counsel for the coal companies, on Dec. 4, the Supreme Court asked attorneys representing the state not to present oral argument. This is the usual course in cases where the court is convinced that there is no material merit in the appeal.

At its last term the Supreme Court upheld the constitutionality of this tax on anthracite levied by the State of Pennsylvania, which had been challenged by a number of mining companies on the ground that it was a tax on interstate commerce. At that time the court held that coal is a local commodity until placed on cars for interstate shipment, and that the tax was constitutional because it applied on coal before being loaded.

Following this decision a number of anthracite operators brought a new test case, the one just presented the Supreme Court. In effect, the basis of this action was that the state tax was applied by the weight of the coal; that it was not weighed as raised at the mines, no scales for the purpose being available, but was weighed in the cars after having been loaded for interstate shipment, therefore giving it an interstate commerce nature. The lower courts held that the time of weighing was a matter of convenience and an incident.

## Output and Value of Coal from Ohio Mines in 1923

## Scranton Companies Reject Higher Tax Valuations

Scranton, Pa., Dec. 8.—Coal companies of Scranton have practically rejected a request by the city administration that they agree to pay additional 1924 assessments representing a tax on a coal land valuation higher than \$200 per foot acre, the figure on which the payments have thus far been based. The city treasury is in financial difficulties and it is understood that counsel for the coal companies have agreed to come to the rescue, but will not consider any further tax payments if they are to be construed as an agreement to a higher assessment than the \$200 valuation. The coal companies in a formal appeal to court are protesting the increased valuation of their coal lands by the city and do not want to prejudice their case by paying on the new valuation.

## S. G. Memory Moves Up in D. L. & W. Coal Co.

Samuel G. Memory, who was sales agent for the Delaware, Lackawanna & Western Coal Co. in Newark for fourteen years, has been elected a vice-president of the company, with offices at 120 Broadway, New York, according to an announcement by Eliot Farley, president of the company. Mr. Memory will have general supervision over line sales and coal handling facilities. H. A. Smith, connected with the company for six years at the New York office, has been re-elected a vice-president.

Mr. Memory's successor as sales agent at the Newark office is A. W. Decker, for twelve years superintendent of the Newark pockets of the company, but more recently connected with the Scranton agency. A. H. Pace is the new sales agent at Scranton and the estate of L. R. Schenck has been appointed sales agent at Toledo, Ohio.

## 21 Miners Rescued, 1 Killed In Nova Scotia Cave-in

A series of shocks that resembled an earthquake caused a cave-in of the roof of the Springfield Mine, near Amherst, N. S., Dec. 6, entombing twenty-two miners. After more than three hours' digging twenty-one of the men were rescued and the body of John Sweeney was recovered on Sunday. The heavy fall of earth took place on the 5,400 ft. level. Four shocks in quick succession brought down the roof of the mine, cutting off the miners working at this point and crushing Sweeney beneath the debris.

## U. P. Coal Co. Standardizes Practice for Safety

The Union Pacific Coal Co. has undertaken the preparation of a complete set of standards to be compiled for the use of superintendents and foremen, above and below ground, to govern all underground installations, including pump stations, transformer stations, motor generator substations, underground hoist installations, electric transmission and trolley line installation, bonding, standard track layouts, including standard switches, frogs and turnouts, standard rock dust barrier troughs, methods of underground rock dusting, etc. The purpose is to provide plans for the initial installation of all tracks, electric lines, underground construction, etc., on a definitely uniform basis, insuring maximum safety, as well as economy in construction and operating costs.

The coal company proposes to draw on the resources of its entire engineering and operating organization, obtaining in addition all possible information and advice from representatives of other companies, past recommendations of mining engineers, expressed through the several associations, etc.

The company has already made real progress for safety. It has substituted improved closed electric lamps for open lights in its seventeen Wyoming mines and has installed a shale pulverizing plant to advance its dusting program.

## Utility Fuel Consumption Up; Power Output at Peak

Electric public utility plants consumed 3,206,083 net tons of coal in October, according to a report by the U. S. Geological Survey, compared with 3,013,184 tons in September, as shown by revised figures. Fuel oil consumed by utilities plants in October totaled 1,401,624 barrels, as against 1,389,264 barrels in September.

The average daily production of electricity by public utility power plants in October was 167,300,000 kw.-hr., which was 4½ per cent greater than the daily output in September and practically equal to the record rate of January.

## Canadian Miners Vote to Form Own Union

Miners employed by the Crow's Nest Pass Coal Co. at Coal Creek and Fernie, B. C., voted to sever connection with the United Mine Workers of America and organize a Canadian union, it was announced following a secret poll on Saturday, Dec. 6.

## Nine Miners Die in Explosion In Welsh Mine

Nine miners were killed in a coal mine explosion Friday morning, Dec. 5, in the Llay Main colliery, near Wrexham, one of the largest mines in North Wales and also considered one of the safest. Ernest Williams, the mine foreman, fired a shot, which was quickly followed by a terrific blast caused by the setting off of a collection of gas.

Five men who were just beyond the range of the fire, gave the alarm and help was at once sent down. The first band of rescuers encountered the deadly firedamp. They were without gas masks, but for two hours they managed to fight the fumes. Eventually the bodies of the victims were recovered.

About 1,400 of the 3,000 men usually employed in the mine had already descended and twenty had got to work near a seam in No. 1 pit when the explosion occurred. It was the third disaster in British coal mines within nine days.

## Missouri Gets Some Scales For Machine Mining

After more than five weeks of conferences between operators and miners of Missouri, a detailed machine scale for the Richmond and Swanwick fields recently was completed in the offices of W. L. A. Johnson, general commissioner of the Southwestern Interstate Coal Operators' Association, Kansas City. The contract is on a basic scale of \$1.15½ a ton plus 14.4c. for pushing. The pushing clause was responsible for the length of the conference.

A detailed machine scale, based on the Richmond scale, also was arranged for the mine of the Mosby Block Coal Co., Mosby, Mo., reopened a little more than a year ago after several years of idleness due to water.

Another contract, one establishing a pick scale on a basis of \$1.92½ a ton at the mine of the St. Joseph Coal & Mining Co., Vibbard, Mo., also was signed during the conference.

## Want Illinois Institutions to Use Coal from That State

United Mine Workers officials of Illinois have issued a statewide appeal to miners and other unionists of the state to use none but Illinois coal. The State Executive Board, President Farrington has announced, instructed August Kerr, chief counsel for the mine workers, to draft a bill for presentation at the next session of the Legislature providing for exclusive use of Illinois coal in state-owned institutions.

A resolution to support this measure will declare: "In some instances municipally and state owned institutions of Illinois are being furnished with coal mined outside the State of Illinois. We believe that it is wrong for the taxpayers' money to be sent outside the State of Illinois to purchase any product which can be furnished in abundance in the state, and we believe that the policy of trading at home should be practiced by the State of Illinois, especially within the state, and produced by Illinois labor."

### Power Plant

Just being completed to supply Teas branch of No. 1 mine, North-East Coal Co., at Thealka, Ky. It comprises two 150-hp. boilers, one feed-water heater, an engine and one 100 kw. direct-current belted generator, this equipment being moved from the exhausted mine No. 2.

## Practical Pointers For Electrical And Mechanical Men

### Welded Cast-Iron Specimens Reveal Strength of Electric Process

THE STRENGTH which may be attained in welding cast-iron parts with a new electrode, without any special heat treatment, has been determined by tests represented in Figs. 1 to 6, inclusive, made by the General Electric Co. The methods of making these tests will no doubt be useful to mining companies which can often

Fig. 1—How the Parts Were Shaped

Most materials can be welded efficiently if the groove to be filled is shaped to form a 90-deg. opening. When this angle is reduced the arc has a tendency to flash to the side of the V and thus not permit the deposited metal to unite the lower parts.

effect large savings by a more general application of electric welding.

Fig. 1 shows two blocks of gray cast iron, beveled along one edge at a 45 deg. angle preliminary to welding. Fig. 2 shows the same block assembled on two steel bars to which they were welded at the outer edges for rigid support. The welding was continuous; in parallel beads and horizontal layers as seen in Fig. 2. Care was taken to obtain suitable overlapping and interpenetration of the beads, but no effort was made to remove slag except by a wire brush which cleaned away the

Fig. 2—One Layer Is Built Up on the Other

Fast welding is not always desirable because it permits the metal to cool too quickly.

Fig. 3—Sectionalized for Tests

The test pieces were obtained by cutting the specimen so that the stresses could be applied properly to the welded material.

loose material. The finished weld was permitted to cool naturally in the air, and then cut away from the steel supporting bars and machined into transverse segments for test specimens, as

Fig. 4—Preparing Material for Test

Layer upon layer of metal was deposited so that a test specimen of the electrode material could be obtained.

shown in Fig. 3. These were turned down to the A.S.T.M. standard dimensions for cast-iron tensile test specimens, except that the length was somewhat increased to include the weld properly between the shoulders of the specimen. As illustrated in Fig. 5, these specimens broke mostly outside of the welds the strength varying from 60 to 90 per cent of the base material. This reduced strength is due to the effect of the welding heat upon the cast-iron base material. Welds made under the same conditions with a standard bare electrode broke away from the cast iron during cooling because the deposited metal was not sufficiently ductile to release the internal strains set up in the weld.

Fig. 4 shows a block of metal deposited on a steel plate by the welding electrode for the purpose of obtaining

Fig. 5—How the Specimen Broke

Note that the deposited material did not break, instead, the fracture was in the material adjacent to the weld.

specimens for tensile tests. The plate was then cut away and the block cut up and machined into specimens and tested. The appearance after test is illustrated by Fig. 6, the ductility of the metal

Fig. 6—Welding Rod Material Stretched

Note that the specimen elongated when tested. This proves the high ductility of the metal.

being shown by the elongation and reduction of cross section near the point of rupture. The test showed the following results:

Specimen	Ultimate Tensile Strength Lb. per Sq. In.	Yield Point Lb. per Sq. In.	Per Cent Elongation in 2 In.	Per Cent Reduction of Area
1	59,300	46,700	12½	13.3
2	54,800	45,700	11	18.2
3	59,000	45,600	12	21.8

### Conveyor Necessitates Use of Improvised Lubricator

It is always a problem to lubricate small moving parts so that each will receive the necessary oil to keep it working freely. At one of the Consolidated Coal Co.'s mines near St. Louis, the loading boom, like many others, consists of sections which travel on small iron rollers. Each of these rollers must be continually lubricated to prevent undue friction and wear. It would be unduly expensive to keep a man on the job to lubricate these parts, so the mechanics designed an automatic lubricator for the purpose.

As shown in the illustration, Fig. 1, the lubricator is made of a piece of pipe and pipe fittings. The ends of a short section of pipe of about 4 in. diameter were fitted with couplings and plugs. The bottom plug was tapped to admit a small piece of ½-in. pipe which leads to a valve and then to a leather wick. The piece of leather is of such length that it just reaches the top of the rollers of the loading boom. As each roller goes by, it wipes the oil off the wick and is thoroughly lubricated. The valve controls the quantity of oil flowing to the wick and is necessary because the viscosity of the oil changes from time to time. In summer, when

## Motor Easily Screened Off from Dust

Next to vibration and leakage of oil, dust causes more damage to equipment than anything else. Herewith is illustrated a cover used to screen off a motor from particles of coal which might otherwise easily fall upon it and damage the insulation.

The top part of this housing is made of sheet iron formed into the shape of an arch. At both ends is a screen which permits sufficient air to pass through the motor but prevents large

**Housing Protects Machine Against Dust and Dirt**

A piece of sheet iron and two pieces of wire screen were the only parts necessary to make this housing.

pieces of falling material from getting on the windings or the commutator. Much of the dust in the air clings to the screen and is thus prevented from settling on the motor. Housings of this type, and all housings in general, must be applied to motors only after the heating characteristics of the motor have been thoroughly investigated. If it is already heavily loaded, a screen

or covering cannot be applied unless some means is provided for obtaining proper ventilation. Most housings obstruct the circulation of air and thus cause the motor to heat unduly even under light load.

## Prevents Coal from Breaking

Operators have long despaired of the possibility of sloping chutes and screens in such a manner that the coal would move steadily forward and yet would not travel so fast as to break up unduly. The speed with which coal travels over a screen influences its action and usefulness. When coal bounds forward at a high rate of speed it bounces over the holes of the screen

**Fig. 1—Wood Retarders Slow Down Coal**

Pieces of wood fastened to a through bolt prevent the coal from passing too quickly down the chute.

and therefore is not properly sized. A more serious difficulty, however, is the breaking down or degradation of the coal when it bumps against obstructions or jostles other coal. Again, if coal is traveling at a high velocity when it drops into the bin, it breaks up considerably.

Many ingenious methods have been

**Fig. 2—Chains Slow Down Coal**

The chains are fastened to the screen by hooks. By increasing the number of such chains the coal may be retarded making the sizing better and lessening breakage.

employed to slow down the speed of coal. Fig. 1 shows wooden retarders set in a chute. The spacing and number of retarders is easily varied to control the speed of the coal. Fig. 2 illustrates chains with hooks at each end which can be attached to the screen jacket. By applying more or fewer of these chains the coal passing over the jacket may be speeded up or retarded.

**Fig. 1—Ingenious Lubricator Made of Pipe Fittings**

A few simple parts to be found around almost any mine make up this little device. Dust and dirt are kept out of the oil the flow of which is regulated by a valve. The leather wicks the part to be lubricated and each receives its proper quantity of oil.

the oil runs freely, the valve is kept nearly closed, but in winter the valve must be opened sufficiently to give the proper flow. The plug at the top of the lubricator excludes all dust and dirt from the oil. Occasionally a few quarts of oil are put in the lubricator and the top screwed on. Little or no attention is required because the device when once adjusted works automatically. The leather wick is constantly covered with oil.

**Fig. 2—Traveling Parts All Require Lubrication**

As the failure of any part of a conveyor shuts down the whole line, this one is provided with necessary lubrication by an automatic oiling device made at the mine and illustrated in Fig. 1. The lubricator works at all times regardless of the position of the boom.

## Problems In Underground Management

### Car Holds Rock for Gob, Clay for Shots or Serves As a Platform for Mixing

A specially constructed clean-up car, which also serves several other purposes, is being used in the mines of the Island Creek Coal Co., of Holden, W. Va. The body is fabricated of 4-in. steel plate, braced with su table angles and straps and mounted on a standard mine-car truck. Details of its construction may be seen in the accompanying illustration.

Double 3x6-in. crosspieces, or joists, rest on the floor of the regular truck and support the steel body of this car. The lower blocks are as long as the truck floor is wide, and the upper pieces extend out over the wheels and support the floor plate of the steel body. This floor plate is made in one piece so that a smooth surface is afforded for shoveling. The ends of the car body are stiffened and joined securely to the floor of the truck by means of steel straps.

#### SIDES EASILY DETACHED

Each of the two sides can be completely detached from the car by releasing a set of hook latches. This allows the side to swing away from the ends and disengage its three keepers. Each of these consists of a U-shaped bracket, attached to the wooden cross-supports, into which fits a strap-lug, or tongue, fastened to the lower edge of

the side plate. This car has a capacity of 100 cu.ft. Its greatest use has been the transportation of gob material to abandoned rooms. Here the load is quickly discharged by easy shoveling from the flat floor plate after the sides have been dropped. It is also useful for carrying clay tamping to the working places from the outside of the mine. With the sides removed the one-piece floor makes an excellent platform for mixing concrete for use in the building of stoppings, overcasts and similar underground structures.

### Pennsylvania Roof Hazard Is Greatest in Morning

At a meeting of Pennsylvania state anthracite inspectors with Secretary Joseph J. Walsh, at Sunbury, Pa. earlier this month a letter was drafted that points out the preponderance of accidents due to falls of roof that occur in the early hours of the day. A similar letter to bituminous operators was drawn up in a meeting of bituminous state mine inspectors in Pittsburgh, on Oct. 15. The contents of these letters discloses the following facts:

During the first eight months of this year 144 fatal accidents in the anthracite mines and 122 fatal accidents in the bituminous mines were caused by falls of roof and coal. Of these, 76 in the anthracite mines and 43 in the bituminous mines occurred before an examination of the working places had

been made by the mine foreman or his assistants, while 16 in the anthracite mines and 15 in the bituminous mines took place shortly after an examination.

In the anthracite mines 65 per cent, and in the bituminous mines 60 per cent of the accidents due to falls of roof occurred between the hours 7:30 and 11 a.m., during which time in all the mines only 35 per cent of the official visits of the day were made. These facts clearly indicate that the number of accidents due to falls of roof might be greatly reduced by better supervision of the working places.

#### DAILY EXAMINATIONS URGED

Resolutions directed to the mine owners were drawn up by both bodies of inspectors urging the examination and making safe of every working place each day before 11 a.m. The resolutions admonish the mine officials who depend solely on observation in judging the condition of the roof in working places and recommend the use of a bar always for making the tests.

### Safety on Inclined Planes

Since a disaster occurred at East slope of the Nunnery mine, near Sheffield, England, one of the engine planes in that mine has been equipped with a device consisting of five specially built cars, fitted with tight couplings and springs to absorb shock. This has been placed in front of the man trip. The leading car of the five carries a strong sharply pointed iron sprag in suspension ready to be dropped in case of necessity. This car also carries about 1,000 lb. of scrap iron to give it the necessary stability. The iron sprag is connected by a cable to simple apparatus in the fifth car by which the former can be released by the operative and made to fall to the floor of the entry should the trip get out of control or the haulage rope break. The car in which the operative rides is padded, and he is secured to his seat by a broad strap around the waist to prevent him from being jerked upwards or out of the car.

Another device, which is being used is entirely mechanical. In this also five specially designed cars are required. The apparatus is placed on a steel frame running on wheels and consists of two pairs of sprags or forks, one pair pointing upward and the other downward and designed to grip the roof and floor of the entry respectively. The projecting sprags are controlled by a governor set so as to bring them into action if a predetermined speed is exceeded.

Most Mine Cars Are Boxes on Wheels, but This One is Different

When the sides are removed by detaching the hooks at either end the car is a one-piece flat plate mounted on wheels and forms an excellent platform upon which to mix concrete for underground structures.

# Production And the Market

## Soft-Coal Business Fitful as the Weather; Anthracite Trade Softens

With only fitful touches of cold weather here and there the bituminous coal trade exhibits marked irregularity. The spurt in the Middle West faded away almost as quickly as it appeared and inactivity best describes conditions there now, as it does also in Ohio and Kentucky. The situation in New England is somewhat the same only much worse. Business in Atlantic coast markets, the Southwest and the Northwest is somewhat better, especially in the last named section, where the lake season is making a Garrison finish; November shipments inland for November, in fact, are said to have been the largest in any one month during the last two years. Though total shipments are far behind those of a year ago the carryover to this season was such as to bring the supply up to normal requirements. The cessation of shipments to the lakes has hit production hard in the Ohio fields and much distress coal has reappeared, and it sells at figures that tend to demoralize prices.

General industry continues to show slow but steady improvement, iron and steel production in particular reporting pronounced gains. Perhaps the most promising development since last spring, however, was the announcement that 116 Fall River cotton mills employing 20,000 workers were to resume operations this week on full time—and without any reduction in wages. Some of these plants have been closed for many months. Only five mills will remain closed.

### Hard Coal Trade Fair but Featureless

The situation in the anthracite trade has undergone little change—business is not bad, but it could be much better without breaking any records. Stove is in strongest demand, except in Philadelphia, where chest-

nut is in the van, but egg and pea move only with difficulty. Steam sizes are only moderately active, buckwheat showing a slight improvement. One of the old line companies has advanced the price of stove 25c. and another has tacked on the same amount for chestnut for December. Independent quotations are unchanged except for a 25c. cut on egg.

Coal Age Index of spot prices of bituminous coal holds its gain of a week ago, standing on Dec. 8 at 171, the corresponding price for which is \$2.07, the same as on Dec. 1.

Activity at Hampton Roads registered the biggest increase since the second week in July, dumpings of coal for all accounts during the week ended Dec. 4 totaling 433,722 net tons, the highest of the current coal year. This compares with 299,555 tons dumped during the previous week.

### Bituminous Output Higher Than a Year Ago

Production of bituminous coal during the week ended Nov. 29, according to the Geological Survey, was 9,646,000 net tons, a decline of 913,000 tons from the total for the preceding week, when 10,559,000 tons was produced as shown by revised figures. The decrease in output was due to the Thanksgiving holiday, which was more widely observed than usual in the coal fields. Despite the decline, however, production surpassed that of the corresponding week of last year for the third successive time. Anthracite output also was sharply curtailed by the holiday, the total for the week ended Nov. 29 being 1,611,000 net tons, compared with 1,827,000 tons in the preceding week and 1,691,000 tons during the corresponding week of 1923. Outlaw strikes also continue to limit output.

Estimates of Production		
(Net Tons)		
BITUMINOUS		
	1923	1924
Nov. 15.....	9,717,000	10,129,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.		

## Midwest Inactive

Mild weather has done it again to the domestic market of the Midwest. There is no heavy buying in any quarter of the region though a snow and sleet storm through parts of Iowa and the Northwest was expected to improve the takings in those territories. The domestic sag has been marked enough to influence steam coal slightly. It is a fact that most big steam consumers are getting a full supply on contracts running the rest of the winter, but small steam trade is paying a shade more than last week.

Pocahontas and anthracite trade in the Midwest is dropping along without high lights and without change in prices. Good smokeless mine run is available at \$1.75 and none of it tops \$2. Lump and egg smokeless is slow at \$3.75.

A little seasonable weather caused a little demand in St. Louis but nothing to create any unusual stir-up. Most orders are small and the demand is mostly for high-grade coal. Country domestic shows a little improvement over the past three weeks. Country steam is slow while local carload is fair and wagonload is good. There are no changes in prices.

## Kentucky Not Busy

The Kentucky coal market hasn't shown any improvement over the week. Prices are a shade weaker, except on screenings, which are in good demand, lighter production, and are commanding steady prices in eastern Kentucky and better prices in western Kentucky. Prepared prices also

have slumped somewhat, the eastern Kentucky market being around \$2.75@\$.3 on best block coals, with a few of the specialty blocks quoted at slightly above \$.3. Western Kentucky 6-in. block worked lower and can be had at \$2.50@\$.275. Lump sizes are around \$2.40@\$.260 in western and \$2.25@\$.275 in eastern, with egg at \$2@\$.250 for western and \$1.75@\$.215 for eastern. Nut is \$1.60@\$.2 in either field and mine run \$1.50@\$.175. Screenings are 85c.@\$.110 for eastern Kentucky and \$1@\$.125 for western.

Colder weather over the week has created a somewhat better demand from the rural districts, where dealers haven't much stock and where farmers buy in hand to mouth lots, or buy late in the season. City retailers as a rule are not buying much replacement fuel.

Gas and electric companies are carrying peak loads and are buying very well and there is a general movement to industrial and heating plants. The brick and cement companies also are unusually busy.

The mines that have opened in the western Kentucky strike zone have not worked up much production and have trouble marketing what they do produce.

## Northwest Trade Is Active

Business has been rushing at Duluth lately, and dock men admit that when the final tally of dock shipments inland for November is in they expect to find the biggest month in two years. It is estimated that at least 27,000 cars left the docks last month. The general tone is optimistic and

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

Index	1924			1923
	Dec. 8	Dec. 1	Nov. 24	Dec. 10
Weighted average price	171	171	170	180
	\$2.07	\$2.07	\$2.06	\$2.18

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

sales seem to justify the high hopes. There has been little contract business despite the rush.

Insurance rates went off Dec. 1, practically stopping dumping at lower Lake ports. Thirty-four cargoes arrived at Duluth last week, of which only one was hard coal, and twelve are reported on the way, of which three are hard. The arrival of the cargoes now on the way will mark the end of shipments this year, as navigation officially closed for departures Dec. 5.

There is a regular boycott on hard coal at the Head-of-the-Lakes. Consumers buy nearly anything in the soft coal line rather than pay the anthracite price asked. Pocahontas is gone except for the favored few who know the way to the coal man's heart, and other brands of smokeless and semi-smokeless are in demand. The big run reported in the east on Pocahontas has cut down the dock supply.

The Milwaukee market experienced no change during last week. Activity depends upon the weather, which of late has been a little more favorable for dealers in fuel. Only a few more lake cargoes are expected at Milwaukee. Receipts for the year up to and including Dec. 3 total 788,862 tons of anthracite and 2,532,970 tons of bituminous coal—3,321,832 tons in all. During the same period of 1923 the receipts were 958,124 tons of anthracite and 3,204,772 tons of bituminous coal, a total of 4,162,896 tons.

### West Gets Stronger

Signs of convalescence are noticeable in the Southwest, where the market has been suffering from warm weather anemia. As yet the improvement has had slight effect upon working time at the mines, but retail supplies are rapidly diminishing, and within a few weeks operators expect their

mines to be back on a full time basis. The demand for screenings is still disproportionately strong. Kansas screenings are selling generally at \$2.25, with some as high as \$2.35. Arkansas semi-anthracite screenings, which not long ago were offered at \$1, are now quoted at between \$1.75 and \$2. Kansas lump, the list price for which is \$5 a ton, is being sold at as low as \$4.50.

In the Utah coal fields production continues at 60 per cent. Colder weather has stimulated demand for slack for heating purposes. The metal mining industry is the largest consumer of coal among the industrials. Business is improving in most of the territory served by Salt Lake City coal producers beyond the borders of the state. Prices, both retail and wholesale, remain steady.

### Ohio Markets Are Spotty

Complete lapse of lake buying, shrinkage of domestic demand due to occasional mild weather, and the usual disposition of manufacturers to withhold purchases during December, have combined with an oversupply to make the Cincinnati market weak on all grades of fuel except by-product coals, which are in good demand and holding firm. Distress coal is offered at demoralizing prices, congestion is reported at the railroad transfer points and the mine tracks are full of loaded cars waiting for a call for numbers.

Kentucky L. & N. operators have resumed all-rail fuel shipments to Iowa, Minnesota and the Dakotas, their differential having been restored on the postponement of the hearing of the appeal of the C. & O. and N. & W. shippers to be let in on the lower rate and the tactical request of L. & N. shippers for a further cut. The I. C. C. was to have heard the case on Dec. 4, but put it over to January.

Output has fallen off markedly in eastern Ohio, due to cessation of shipments to the lakes and the languid industrial situation. At Cleveland slack and nut-and-slack continue to be scarce and the price remains firm at the high figures of last week. Inquiries for all other grades are very quiet. In the domestic market retail dealers are well stocked, with little disposition to make further commitments until consumers draw more heavily upon these stocks.

Trade at Columbus has been spotty during the past week, especially in domestic, which apparently has been stimulated by colder weather, though there are still quite a few cancellations. Prices for domestic sizes are rather steady at recent levels. Smokeless is noticeably slower although prices have not been reduced. Retail trade has been rather good but dealers have fairly large stocks and in some cases are not yet inclined to replenish them. Retail prices are steady and little cutting is reported. Industrial conditions have improved somewhat, and this has been reflected in the steam demand. Less demurrage coal is in evidence, which has relieved the situation to a certain extent. Production in the Hocking Valley is at about 20 per cent of capacity. Pomeroy, Jackson, Cambridge and Crooksville are doing only slightly better.

### Pittsburgh Market in Doldrums

The Pittsburgh market shows no signs of recovery from the depression which struck it late in October. Shipments of operators to regular consumers are proceeding much as formerly, but there is very little inquiry in the spot market, and demand from all retail dealers is poor. Railroad operations are heavy and industrial operations are moderately heavy. The steel industry is running at about 75 per cent, against 66 per cent in October. Prices are unchanged.

Coal production in the central Pennsylvania bituminous field in November totaled 59,114 carloads compared with 66,792 in October. The drop was due largely to a number of holidays on which the mines were idle. The rate of production was about the same, considering the number of days worked. No bill cars reported at the close of the month were 1,200. Prices range as follows: Pool 11, \$1.70@ \$1.80; pool 10, \$1.85@ \$2.10; pool 9, \$2.15@ \$2.25; pool 71, \$2.35@ \$2.40; pool 1, \$2.40@ \$2.65.

Winter weather has improved Buffalo's coal trade all through. Prices, however, are unchanged, except for slack, which is stronger, some shippers asking 10 to 15c. more for it, due to the closing of the lakes. West Virginia and Kentucky coals, paying much higher freight than any from Pennsylvania, are finding their way here. The movement of all freight, including coal, is still good. The lake trade is about at an end, shipments for the week being only four cargoes, totaling 31,400 tons.

## New England Has Discouraging Outlook

To the steam trade in New England the outlook is anything but encouraging. Not only are prices drooping but there is very little buying interest discoverable in any quarter. Purchases of a few weeks ago are by this time fully delivered and it is likely that there will be renewed accumulations at the Hampton Roads piers. It has long been the practice of smokeless agencies to send coal to tidewater when the Western and line trades slacken, and this season is no exception. What meager inquiry develops is discriminating as between coals. Slack is offering freely, with prices 30@40c. less than mine run of equal grade, but there is so much high volatile slack available that sales are few and far between.

Owing to the dull market and the discontinuance of pool designations Pocahontas and New River mine run coal of recognized grade can be had from \$4.25 down to \$4 flat, and there are rumors of somewhat higher ash coals selling at less than the \$4 level. Off-shore business also is light and coastwise tonnage is falling off as the 60 to 90 day purchases are being filled.

On cars Boston the price curve has dipped in sympathy with going figures at Hampton Roads. High grade smokeless coals are to be had at \$5.25@\$5.50 per gross ton, but sales at the latter level are special or are confined to single carload lots.

All-rail from central Pennsylvania there is no perceptible change. In the always widening territory open to Pocahontas and New River from tidewater there is an ample tonnage of Cambria and Clearfield coals offering at the same low range that has been characteristic the whole season. Dumpings via the New York and Philadelphia piers are light.

## Buyers Perk Up in Atlantic Markets

Buyers showed more interest in the market at New York last week, but orders were not heavy. The better grades are scarce, as the spot buyer is not willing to take the poorer grades when he can obtain better coals at a trifle higher cost. Contract holders are taking their full requirements, leaving comparatively little coal for the occasional buyer. Although reports show a daily average of about 1,700 cars of coal at the piers at New York there is no distress coal around, shippers being able to dispose of all surplus coal without much trouble.

While demand at Philadelphia is not particularly active, considerable tonnage is moving. Many mines are doing better now than for months past. Railroads are active buyers and their stockpiles are growing. The average consumer, however, is cautious. There are signs of improving trade, and this is giving the buyer more courage to take in more than current requirements. Prices are unchanged.

Demand has not improved at Baltimore, the situation remaining as it has been for some time past, with no change in prices. November proved to be the lightest export month for coal for the present year, falling far behind Novembers of other years.

The trade at Birmingham is virtually marking time awaiting some development to stimulate demand. The recent cold weather was not of sufficient intensity or duration to benefit the wholesale market to any marked extent, and though yards moved considerable fuel to householders in small lots their reserves were not seriously crippled and they are taking on very little coal from the mines. Spot market business is scarce and much solicitation is required to move the domestic production. Steam consumption has

not increased in several weeks past as inquiry from industrial sources has not been up to expectations, the spot supply being absorbed principally by operations of a seasonal character.

## Anthracite Trade Slips Some More

The anthracite market at New York is not as active as it might be. Stove and chestnut move easily but egg and pea are becoming more difficult to move daily. Retailers are prepared to take care of a reasonable increase in orders, as they are well supplied with all sizes except stove. Last week they increased the retail price for stove and chestnut 25c. per ton, making the price in Manhattan \$14.25. No other prices were changed. On Dec. 1 one of the old-line companies increased its price for stove 25c. per ton and another advanced chestnut the same amount. Independent quotations, except for egg, have not been affected by the lull, but a cut in output is expected to affect these coals. There is not much activity in steam coals.

A few cool days in Philadelphia brought retailers actively into the market, but only for a short time. Dealers' demand for nut has greatly strengthened and the call for stove is fairly strong, but egg and pea are slow movers. Steam sizes are fairly well taken, with the demand for buckwheat a bit better than last week.

A real touch of winter at Baltimore has awakened demand for hard coal. There is no scarcity of fuel here, however, and dealers are moving orders promptly. Due to delay in shipment of apparatus, the exhibit of appliances to educate the public in the use of steam coals has been held off for a few days.

The situation at Buffalo is good, but the demand is not large enough to make up the shortage that has existed all summer. The use of the smaller sizes is increasing, as the consumer is finding that he can put in buckwheat for banking at night or for choking down fires that have gone too high and at a cost only a trifle over half that of the regular sizes. The coke trade is light. Some wholesale shippers report a fair trade to certain parts of Canada, but the Buffalo trade does not improve much.

## Coke Market Stiffens

The first quarter contracting movement in Connellsville furnace coke has turned out to be a very remarkable one, totaling about 225,000 net tons a month, and prices advanced sharply during the movement from \$3.25 to \$4 for a recent contract. Apparently all the furnaces now in operation, or definitely scheduled to blow in, such as use purchased Connellsville coke, are covered, but there is some inquiry on the part of idle furnaces considering the question of going in. The sales do not by any means take up the merchant capacity of the region, but they take up pretty well all that can be gotten into operation promptly. The spot furnace coke market in the past week has developed a little demand, recent lots going at \$3.50. Spot foundry coke has been in poor demand, being still quotable at \$4@\$4.50. Heating coke is quotable all the way from \$2.60 to \$3.

## Foreign Market And Export News

### Inquiry Stronger in British Market; Contracting Picks Up

Business is better and inquiry stronger in the South Wales coal markets than for several months. Shipments also have increased owing to a better supply of shipping tonnage. The market still is unsatisfactory and, though some collieries have been able to increase the number of shifts operated, many are still on short time.

The greatest concern to the South Wales operator now is German competition in Europe. German miners are working nine hours a day at a low wage, so that German coal is available at a much lower rate than British. In addition the German operators have opened up depots in South America and Portugal, and are doing their utmost to procure business to an extent which will insure full working time for the German mines. German operators also are offering ship owners sixty days' credit on bunker coal, so that a round trip voyage can be made before

the coal is paid for. In South Wales the collieries ask for payment in seven days, so that the weight of German competition is felt more than ever.

In North England business has been steady since last week, though it is still below normal. Orders for more than 1,000,000 tons of second admiralty qualities have been placed by one factor at about 25s. 3d. f.o.b., but he is now asking a material advance. French railways have booked large quantities over the first half of 1925. Contracts aggregating 70,000 tons of gas coals have been placed at Newcastle, but Germany has obtained the order for 30,000 tons of steam coals for the Lithuanian State Rys.

Production by British collieries in the week ended Nov. 22, a cable to *Coal Age* states, was 5,309,000 tons, according to official reports. This compares with 5,232,000 tons produced in the preceding week.

### French Industrial Coal More Active; House Grades Quiet

Save for a slight improvement in industrial fuel the French coal market continues unchanged. After being more active last week, the demand for house coal is again quiet, due to mild weather.

In the East, supplies of industrial beans are plentiful and competition for business is keen. The marketing of patent fuel is heavy, in spite of further price concessions.

Arrivals from South Wales have been normal of late.

From Nov. 1 to 16, France and Luxemburg received 172,600 tons of indemnity fuel, consisting of 115,500 tons of coal, 38,200 tons of coke, 18,900 tons of lignite briquets, a daily average of 10,800 tons, compared with 28,550 tons in October.

During the first eighteen days of November receipts of indemnity coke aggregated 36,932 tons. Since then,

however, deliveries have recovered their normal pace and arrivals between Nov. 19 and 25 inclusive were 73,035 tons.

### Trade in All Lines but Bunkers Slow at Hampton Roads

Hampton Roads business is dull, with the market weakening and demand dropping off. Foreign trade is at a very low ebb and coastwise movement and bunker trade are barely holding their own.

Inquiries have fallen off and the market lacks stimulus. Domestic business is holding fairly strong in the retail trade, with increasing cold weather having a tendency to hold prices and keep up demand.

The bunker trade alone is being depended on to keep the piers moving at full time. Movement from the mines is regular and considerably above the demand. Very little spot business is being transacted.

## News Items From Field and Trade

### ALABAMA

Reports reaching Jasper are that the De Bardeleben Coal Co. has begun active work on its new \$100,000 coal washer at Empire. It is stated the company will also erect a new modern tipple near the new washer.

The Sloss Sheffield Steel & Iron Co. assumed control and operation of the physical properties of the Alabama Company on Dec. 1, announcement being made that one of the idle stacks of the latter at Alabama City will be made ready for operation Jan. 1. The Alabama Company had active coal mining operations at Mary Lee, Jefferson County, and at Searles and Brookwood, Tuscaloosa County.

Details of the merger of the properties of the Pratt Consolidated Coal Co. with those of the Alabama By-Product Corporation have been worked out, as the consolidation has been approved by the stockholders of the respective companies. The properties will be operated as the Alabama By-Product Corporation with Morris Bush, president; Horace Hammond, A. P. Bush and Carr McCormack, vice-presidents; J. A. Shook, secretary; H. L. Morrow, treasurer; H. M. Cowart, assistant secretary and assistant treasurer. G. B. McCormack is chairman of the board, which is composed of the above officers with the exception of Mr. Cowart and the addition of Erskine Ramsay. No new financing was necessary according to official statement, ample cash being in hand for working capital and such expansion and improvements as may be contemplated for the near future.

### COLORADO

J. B. Marks, purchasing agent of the Colorado Fuel & Iron Co., has been named assistant to President Welborn to take over some of the work performed by Fred Farrar, who recently resigned as vice-president. Mr. Marks continues also as purchasing agent.

A decision was handed down by the State Industrial Commission in favor of the owners and operators of the Morning Glory mine, near Walsenburg, in Huerfano County, in a dispute between the miners and operators as to charges for recharging the storage batteries used for the miners' electric cap lamps. Several months ago a state mine inspector ordered the change from carbide to electric lamps because of gas in the mine. The operators deduct \$2 a month from each miners' pay for recharging the batteries. A number of

workers quit one day in protest, but the next day returned to work after agreeing to submit the matter to arbitration before the State Industrial Commission. The commission held that the charge is fair and reasonable. On a complaint of the miners that the operators had been, in a few isolated cases, changing wages without due notice, the commission also ruled in favor of the employers.

### ILLINOIS

The Fallon Coal Mines Co., of O'Fallon, has been petitioned in receivership by the Security Trust Co., of Detroit. The Belleville Savings Bank, of Belleville, has been appointed receiver. Most of the stock and bonds of this company is owned by Michigan people. The Detroit bank is foreclosing on a mortgage.

The washhouse of Mine A of the Central Illinois Coal Mining Co., a few miles west of Springfield, was destroyed by fire a few days ago, with its contents and with the clothes of the 130 miners employed. A carload of powder was on a nearby siding but the wind carried the fire away from the car.

The Donk Bros. Coal & Coke Co. railroad, the St. Louis, Troy & Eastern, has been purchased by the Illinois Light & Power Co. This road has operated 18 miles of track from Troy to East St. Louis and a 7-mile spur from Edwardsville to Formosa. The purchase also included the Illinois Belt Ry., a small switching line in East St. Louis.

### INDIANA

The Indiana Public Service Commission soon will hear the petition of miners about Blackhawk for a change in miners' train service on the C. M. & St. P. R.R. The case dates back several months when the railroad discontinued operation of the train because of lack of business in the coal industry. Later partial service was restored but the cars of the miners' train, which are left on a siding, are picked up by a passenger train and taken to Terre Haute. The miners say sometimes they are compelled to wait an hour or more for the passenger train.

### KENTUCKY

It is reported that certain political and newspaper interests of Kentucky are starting a fresh fight for a coal tonnage tax to come up in the 1926 session of the Legislature, but a few newspapers are combating the move-

ment and endeavoring to show that the coal business has been in a bad way without any taxes to add to the complications of competitive conditions north of the Ohio River.

C. J. Neekamp, secretary of the Northeastern Kentucky Coal Operators Association, Ashland, was re-elected chairman of the Coal & Coke Committee of the Ohio Valley Shippers Regional Advisory Board at the annual meeting held in Louisville on Nov. 25. At this meeting Mr. Neekamp reported for his committee, and stated that the Kentucky and Virginia section would need more coal cars over the next ninety days than was the case last year.

The Kentucky River Coal Corporation is about to erect a store building in Heiner.

The Hatcher Coal Co., near Pikeville, suffered fire loss of about \$16,000 when the headhouse and part of its chute were burned at night on Nov. 19.

It is reported from Paducah, that the First District Educational Association, meeting there on Nov. 29, after discussion on recommendation of the finance committee, adopted resolutions favoring a state tax on coal, a percentage of the tax return to be paid to the state school funds.

The Gorman-Pursiful Coal Co. is about to let the contract for a store building in Whitesburg, Ky.

The Coil Coal Co., Madisonville, operators, recently contracted the tonnage of the Co-operative Coal Co., at Nebo, effective Dec. 1. The capacity is about 1,000 tons daily.

### MINNESOTA

Announcement was made last week of the wedding of Henry E. Smith, vice-president of the M. A. Hanna Coal & Dock Co., St. Paul, and Mrs. E. H. Windom, of Duluth. The wedding occurred at Dellwood, on White Bear Lake.

### NEW YORK

Net earnings of the United States Distributing Corporation for the two months ended Oct. 31 were \$248,170, against \$133,204 for the two corresponding months in 1923, or a gain of 85 per cent, according to President Harry N. Taylor. "After allowing for the \$192,500 annual preferred dividend requirements," Mr. Taylor said, "these figures indicate annual earnings of better than \$11 a share on the 110,000 shares of common stock of no par value now outstanding."

## OHIO

N. L. Mahan, for many years general manager of the Southern Coal & Coke Co., with executive offices in Cincinnati, Ohio, is now connected with the General Coal Co., Philadelphia, as Western sales manager, located in the Dime Bank Building, Detroit, Mich.

The New York Coal Co., of Columbus, has placed in operation Mine No. 36 at Buchtel, following a shutdown of almost a year. It gives employment to about 150 men. Officials of the company believe that the mine will be operated on full time for the greater part of the winter season.

In the Nelsonville district there are 48 mines operating of which 15 are on railroad fuel. The daily tonnage of the district is about one-fourth normal. Many of the operators say that they are merely holding on and keeping operations going in the hope of better demand in the near future.

## PENNSYLVANIA

The Mid Valley Coal Co., a subsidiary of the Hazle Brook Coal Co., has closed its No. 2 breaker for an indefinite period. It is said to be the intention of the concern to dismantle the breaker and run the coal to the Raven Run operations to be prepared for market. The Mid Valley mine has an output of approximately 800 tons a day.

F. D. Welsh has been appointed superintendent of the Rossiter Mines and property of the Clearfield Bituminous Coal Corporation, of Indiana, Pa., at Rossiter.

Arthur Williams, of Scranton has been appointed superintendent of the Powderly mine of the Hudson Coal Co., at Mayfield. This is one of the largest operations in the anthracite region. Mr. Williams will rank as one of the youngest mine superintendents in the Lackawanna valley.

Newspapers in the anthracite field are carrying reports to the effect that in case John L. Lewis, president of the miners' union, becomes Secretary of Labor under President Coolidge, Philip Murray, of Pittsburgh, will be advanced to the presidency and that a boom probably will be launched to make Thomas Kennedy, of Hazleton, head of District 7 and a member of the Anthracite Conciliation Board, an international vice-president.

E. B. Jermyn, former independent coal operator, has announced himself as a candidate for Mayor of Scranton in 1925.

The American Coke & Fuel Corporation has resumed operations at the Sunshine coal and coke plant, at Martin, Fayette County, after being idle more than a year.

Fourteen workers in mines near Wilkes-Barre, recently were found to possess miners' certificates even though none could show the necessary qualifications. They were immediately directed in court to surrender their papers. Under the Pennsylvania law no anthracite employee can take a test

for a miner's certificate until he has had two years' experience in the industry.

Arthur Etienne, paymaster, and Edward Kelley, mine foreman of the Marion Center Coal Mining Co., Greenwich, Cambria County, were arrested, charged with having "framed" the \$7,000 robbery of the company's payroll, Nov. 28. The police said that both men confessed and that all but \$300 of the loot had been recovered. The authorities said Kelley, disguised, had entered the coal company's office, "assaulted" Etienne and made off with \$7,155. Then, the police said, Kelley walked out of town, removed his disguise and returned home as if nothing had happened.

Charged with violating the state mining law by smoking in a coal mine, Joseph Solgoda of Acosta, Somerset County, was sentenced to pay the costs, a fine of \$90 and serve 90 days in jail by Judge John A. Berkey when he pleaded guilty. The prosecution was brought by Fletcher W. Cunningham, state mine inspector of the Twentieth Bituminous district.

## UTAH

The Liberty Fuel Co., of which George Schultz is superintendent, is building a rescreening plant quite similar to the new one at the Mutual Coal Co.'s mine.

W. H. Homer and Albert Shaw, president and superintendent respectively of the Mutual Coal Co. at Rains, recently completed the installation of a loading boom for lump coal, and a rescreening

Courtesy Bertha-Consumers Co.

### Unusual Gravity Plane at Goucher Mine

Note the force rails that give one the impression that a Barney is used. Not at all! Numbering the rails from left to right the 5-ton loaded monitor in the foreground is running on rails Nos. 1 and 3 and the 5-ton empty monitor in the rear is traveling on rails Nos. 2 and 4. Thus switches but not frogs are eliminated

plant. The loading boom, 48 in. wide, provides facilities for thorough picking. The rescreen consists of a super-capacity continuous elevator, taking the coal from the main shaking screen and delivering it to a set of flexible hanger screens over the bins, each of which has a capacity of 60 tons.

Robert Howard, superintendent of the Peerless Coal Co., has just finished the erection of a commodious nine-room clubhouse at Peerless for the entertainment of officials of the company and others who wish to spend time at the mine. The building is a bungalow with a two-color composition shingle roof. On the main floor are a combination sun parlor and dining room, a kitchen, a hall, six bedrooms, and two baths. In the basement is a recreation room. This clubhouse is considered one of the most attractive buildings in Spring Canyon.

The Rains mine in Carbon County, blown up on Sept. 21, is working regularly again and is producing 1,000 tons a day. Its normal capacity is 1,700 tons, and this amount is expected to be produced after the first week in December, officials stated. The State Mining Department has as yet not issued its report regarding the cause of the explosion in question.

Roy G. Mead and Joel H. Richardson have acquired a lease on 160 acres of coal land in Grand County, following an auction at the State Land Office. They agreed to spend at least \$3,000 on the property and to produce coal commencing with the fourth year amounting to a minimum of 1,600 tons. The government will receive a royalty of 10c. a ton. A premium of \$50 was paid. Messrs. Mead & Richardson are from Los Angeles, Cal.

George A. Storrs, charged, with three others, with fraud in connection with the promotion of the Great Western Coal Mines Co., and under indictment by a federal grand jury, has entered a plea of not guilty in the United States District Court, at Salt Lake City. The defendants were arraigned before Judge Tillman D. Johnson.

## VIRGINIA

The U. S. Shipping Board has awarded to the Willard Sutherland Coal Co. a contract for 1,700 tons of pool 2 coal, for immediate delivery at the Sewalls Point piers at \$3.92 per ton. The figure was regarded as representing a very low market level. The other bidders were Robert Hasler & Co., \$3.93; W. C. Atwater & Co., \$4.04; Dexter-Carpenter Coal Co., \$4.05; W. H. Brown Coal Co., \$4.07; West Virginia Coal Co., \$4.25. The contract figure was not regarded in the trade as indicative of the real market, however, which was held to be nearer \$4@ \$4.10.

## WASHINGTON

Wylie Hemphill, who had been general sales manager of the Pacific Coast Coal Co. at Seattle, has been promoted to the second vice-presidency. He continues as general sales manager also. Mr. Hemphill has just returned from a trip to Europe.

## WEST VIRGINIA

The Morrison Coal Co., owned by the Laing interests and operating mines at Glen Morrison, has presented to its colored employees a church and a lodge hall.

One of the largest store buildings in West Virginia will be opened in the near future by the Pocahontas Fuel Co. at Itmann, just below Mullens. The structure is built of native stone with a garage and warehouse beneath it. The cost of the building and stone wall around it will run well up to \$400,000, it is stated.

Permanent financing of the fourteen-story Coal Exchange Building, in Huntington, has been arranged for. The structure will be completed about Feb. 1. and will cost about a million dollars. S. W. Straus & Co., of New York, have underwritten an issue of \$600,000 first mortgage 6 per cent serial coupon gold bonds, to be secured by the land and the building now in course of erection. A large proportion of the rentable space in the building has already been leased. D. C. Schonthal, A. Solef, M. A. Zeller and H. A. Glick are officers of the building company.

In connection with the effort of the government to collect \$38,653.90 alleged to be due for internal revenue and excess profits taxes from the Knob Coal Co., a subsidiary of the American Gas Coal Co., it has developed that attorneys for the government failed to take an appeal from a decree of sale in the lower court. When an appeal was taken it was only as to the priority of the government's claim for taxes. The Supreme Court ruled that the government did possess the right of priority in its claim for internal revenue and excess profits tax but since there was nothing else asked for, that part of the decision of the lower court ordering a decree of sale was not reversed, so that there is a tangle to be unraveled in the Circuit Court of Monongalia County.

Additional loading facilities are being provided at the Pinnacle mine and the Thomas No. 1 mine, of the Thomas Coal Co. on Crane Creek, by the Norfolk & Western Ry. A new loading track is being installed and existing tracks are being rebuilt. Retaining walls also are being built along the creek bank and the county road right of way in order to prevent a washout in the future such as that which occurred last spring in the Crane Creek section.

Thomas Jones, of Thurmond, has been named as receiver for the New Fire Creek Fuel Co., formerly the Hump Mountain Smokeless Coal Co., of Summers County. Judge J. H. Hatcher, of the Circuit Court of Summers, made the appointment in chambers at Charleston.

Coal companies recently increasing their capital stock were the Kentucky & West Virginia Coal & Mining Co., from \$100,000 to \$500,000; the Superior Harlan Coal Co., from \$250,000 to \$300,000, and the Raleigh-Wyoming Coal Co., from \$4,100,000 to \$4,700,000. The W. H. Green Coal Co., of Elkins,

has decreased its capital stock from \$50,000 to \$25,000.

The Campbells Creek Coal Co. has authorized the resumption of work on the large steel tippie and preparation equipment for the Point Lick mine. This is a new shaft operation and will be one of the largest output mines in the state, the tippie being designed for an output of 600 tons per hour. The complete steel tippie and all equipment is being designed, manufactured and erected by the Fairmont Mining Machinery Co.

The mining town of Yukon, in McDowell County, seat of operations of the Yukon Pocahontas Coal Co., was almost totally destroyed by fire late in November, the loss being estimated at \$100,000. About fifty people were made homeless. The fire, which started in a vacant dwelling near the general store of the company, is thought to have been of incendiary origin. The only buildings remaining after the fire were the company store, one other building and a dwelling.

Orders were received at Gary, operating headquarters of the United States Coal & Coke Co., a subsidiary of the United States Steel Corporation, late in November to increase coal production 5,000 tons per week, it was announced by Colonel Edward O'Toole, general superintendent of the company. A few weeks ago orders for coal were received necessitating the reopening of Mine No. 7, and a little later Mine No. 4 was put in operation.

## WYOMING

The Hellgate Coal Co., a commercial company with headquarters at Denver, Colo., has announced it will soon open its coal properties four miles west of Rawlins. Practically all of its output will be used to supply its Denver trade, though some will be sold to retailing companies outside that city.

It is reported from Corbin that coal trains are moving from there over the Cincinnati division of the Louisville & Nashville R.R. at an average of one every 30 minutes, this coal coming from the big coal companies and industrial mines of southeastern Kentucky, which comes into the division quarters at Corbin. Car supply has been adequate but there hasn't been any surplus motive power, and the Corbin yards have been congested.

## CANADA

A reorganization of the Fundy Coal Co. has been effected. These pits are at Joggins. They have been idle for some time but under the reorganization plans, they will be operated at capacity henceforth. The intention of the new executive is to install new and modern equipment next year that will increase the capacity greatly.

The mines of the Inverness Coal & Railway Co. at Inverness, which have been idle for several months, have resumed operation. As the mines had fallen into disrepair, only 250 men were employed at first, the plan being to enlarge this crew as soon as possible. The management have been able to

interest the miners in a co-operative project, to cut the costs of mining. For the past two years operations in the Inverness mines have been far below capacity owing to inability to show profits. The mines have been closed thrice during that period. According to the management no difficulty is being experienced in marketing the coal.

The Manitoba Department of Public Works has awarded contracts for 36,000 tons of coal for public institutions, the total price involved being \$203,468. This constitutes the bulk of the government requirements until November, 1925. There were in all 57 tenders. Orders for 10,000 tons, 80 per cent of which was from the Souris mines, were distributed among six companies, the prices being for Souris coal, \$3.85; Souris slack, \$3.60; Youghiogheny slack, \$7.34 for delivery on railway siding at Hospital for Mental Diseases, Selkirk. Among the other contracts were these: Capital Coal Co., 6,000 tons of Youghiogheny screenings, \$7.45; Winnipeg Supply & Fuel Co., 5,000 tons Youghiogheny screenings, \$7; Manitoba & Saskatchewan Coal Co., 5,000 tons Souris mine run, \$4; C. J. Sharp & Sons, 3,000 tons Souris mine run, \$4.70 for delivery at Portage la Prairie.

The last week in November was exceptionally busy at the Drumheller mines and, according to indications, many records for daily output and shipment will be broken before the end of the year. On Monday, Nov. 24, 322 cars passed over the Canadian National Ry. scales, being billed to various points in the prairie provinces. This constitutes a record since the mines resumed work in the fall. As a direct result of the increased activity in the Drumheller field, general business conditions are said to be excellent. The pay roll on Saturday, Nov. 22, was \$150,000 which is well above the average for this district.

## New Companies

**The Rio Verde Coal Co.** has been incorporated in Denver, Colo., with a capital stock of \$50,000, by W. D. Waltman, W. O. Gara and M. A. Wogan.

**The Rathbun Coal Co.** has been incorporated in Centerville, Iowa, with a capital stock of \$25,000, by L. B. Harbold and Joseph Swab.

**The McHoma Coal Co.** has been incorporated in McAlester, Okla., with a capital stock of \$25,000, by Egbert D. Buchanan, Roy Caldwell and C. A. Sturgeon.

**Consolidation Coal Lands, Ltd.**, of Coalhurst, Alta., has been incorporated with a capital of 100 shares of no par value to carry on the business of a mining, mineral reduction and development company by Eric A. Lovett, George L. Brockbank, and Thomas C. Boyd.

**Phoenix Coal Co., Ltd.**, has been incorporated with \$40,000 capital and head office in Toronto, Can., to manufacture and deal in fuel. The provisional directors are Grace Cutler, Tavia Shunk and Edible J. Clark.

**Prairie Coal Land, Ltd.**, of Coalhurst, Alta., has been incorporated with a capital of 500 shares of no par value to carry on the business of a mining, mineral reduction and development company by Eric A. Lovett, George L. Brockbank and Thomas C. Boyd.

**The United Bituminous Products Co., Inc.**, New York City, has been chartered at Albany, with \$25,000 capital, to manufacture bituminous products. R. P. Buell, William H. Hall and Max N. Hammerling, 165 Broadway, are the directors and subscribers. Graham, McMahon, Buell and Knox, 165 Broadway, are attorneys for the corporation.

## Traffic

### Short Haul Rate Adjustment Deferred in West Virginia

It has been announced by the Public Service Commission of West Virginia that the proposed adjustment in the short haul freight rate on coal and "coke-in-transit" will not become effective on Dec. 21, as originally fixed, but that the application of the rate had been deferred until Jan. 1. No special reason has been given for the change in the dates but the understanding is that no harm will be done Clarksburg interests by the change. Postponement will not result in a change of the original order, it is understood.

### Rate to East St. Louis Not Likely To Stand

The decision by Judge Crow, at Belleville, Ill., in which a rate to East St. Louis, Ill., of 70c. was made from a group of mines, is looked upon as a joke for the reason that the Judge did not pass on the matter that was presented to him as a whole, but his decision altered that and his action is regarded as rate making, which is beyond the authority of the court. Therefore the application of the low rate is regarded as unconstitutional.

### New York Commission Approves New Fuel Rates

The Public Service Commission of New York has approved a carload rate on coke, minimum weight 40,000 lb., on the Arcade & Attica R.R. from Attica when coming from points on connecting lines to Arcade, Arcade Center, Curriers, Earls, Java Center, Johnsonburg, North Java, Perrys and Varysburg, of 78c. per net ton, effective Dec. 10, 1924. No rates heretofore have been in effect.

New rates of the New York Central (East) on coke in carloads, minimum weight in open cars 50,000 lb. and when in box or stock cars 40,000 lb., also have been approved. Rates per ton from Buffalo, East Buffalo and Harriet to stations as follows: Stafford to Shortville, inclusive, \$1.51; Clifton Springs to Geneva inclusive, \$1.89; Waterloo to Solvay, inclusive, and Corning, \$2.02. Reductions effective Dec. 5, 1924.

The Commission has approved a new joint rate on coal of the Delaware & Hudson R.R. (anthracite, birdseye and bituminous) in carloads from Mechanicville to South Schenectady (on West Shore) of \$1.60 per gross ton, effective Jan. 10, 1925. No joint rate hitherto has been in effect.

## Industrial Notes

The Osgood Company, of Marion, Ohio, announces the appointment of C. J. Thompson as district sales manager in charge of the New York district with offices at 50 Church Street, New York City, effective Dec. 1. Mr. Thompson has had wide experience in the excavating machinery and contracting field.

The Cutler-Hammer Mfg. Co., of Milwaukee, announces the addition to its industrial sales engineering force of the

eastern district of T. E. Beddoe, at one time connected with the Pittsburgh and Chicago offices of the company. He is now located in the Philadelphia office. Paul Darlington, for the past four years in the industrial controller engineering department at the Milwaukee factory, has joined the New York staff.

Foot Bros. Gear & Machine Co. recently completed arrangements with Chas. Bond & Co., Philadelphia, Pa., for the distribution of its IXL gear products and speed reducers in eastern Pennsylvania and Maryland, the state of Delaware and all of New Jersey south of Mercer County.

The Hyman-Michaels Co. of Chicago, due to its expansion in the railway equipment field, has engaged the services of F. W. Glauser, formerly associated with the Mid-Continent Equipment & Machinery Co., of St. Louis. Mr. Glauser will be located in St. Louis, where he will assume the management of the equipment department for the Southern territory.

The Central Steel Co., of Massillon, Ohio, manufacturers of Agathon alloy steels, announce the appointment of A. B. Cooper as their Philadelphia district sales manager with offices in the Widener Building. Mr. Cooper has been identified with the steel industry for 17 years in both operating and sales work and is well known in the Philadelphia territory, where he was formerly identified with the Tacony Steel Co. and the Penn Seaboard Steel Corporation.

## Obituary

Henry P. Adams, well known in the coal industry of southern West Virginia, died late in November at his home near Lynchburg, Va. Mr. Adams was for more than 20 years City Treasurer of Lynchburg but resigned that post a few years ago to devote more attention to his rapidly growing coal interests. He became president of the Ivy White Ash Coal Co., operating at Ivaton, W. Va. He also was vice-president of the Pinnacle Block Coal Co. as well as vice-president of the Imperial Coal Sales Co. of Lynchburg, Va. Surviving him are a wife and three children.

Evan W. Evans, 55, well known mining expert, died Nov. 27 at his home in Scranton following a ten-days' illness that developed into pneumonia. Mr. Evans was for many years mine foreman of the Capouse colliery, of the Scranton Coal Co. He was born in Scranton and began his career as an employee in the coal breaker. While engaged in this work he studied at night, eventually becoming a recognized anthracite authority. He also organized a mining school in West Scranton for the instruction of eager students of limited resources. His course was finally adopted by the Y. M. C. A., and there he continued to help those who desired to prepare for state examinations for mine foremen and superintendents. Surviving him are his wife, four daughters and three sons.

While taking lunch at the Macdonald Hotel, Edmonton, Alta., on Thursday, Nov. 27, Louis Pratt of Montreal, president of the Coal Valley Mining Co., collapsed and died within a few hours from heart failure. A close friend of Premier King, Sir Henry Thornton and other big men and himself a prominent financier in eastern Canada, Mr. Pratt was well known in coal circles. At the time of the fatal seizure he was luncheon with C. E. Berry, his co-director of the Coal Valley Co., with whom he had been spending a few days investigating mining conditions in Alberta. The remains were forwarded to Montreal for burial.

## Coming Meetings

West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

American Institute of Mining and Metallurgical Engineers. Annual meeting, Feb. 16-19, 1925, 29 West 39th St., New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

American Institute of Electrical Engineers. Midwinter convention, Feb. 9-13, 1925, 29 West 39th St., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Self-Fluxing Electrode for Welding Cast Iron

The type A welding electrode is a product of extensive research by the General Electric Co., and it differs radically from other electrodes in its make-up and characteristics. It is a fluxed electrode having a construction that protects the flux from dissipation. The clean metallic surface renders it adaptable to automatic welding equip-

### Flux Combined with Rod

The action of the flux is to assist the deposition of metal and also to prevent oxidation and nitrification. The proper quantity of flux is always applied because it is fed with the welding rod.

Its outstanding features are: Arc stability, ease of manipulation, rapid deposition, good penetration, sound tough welds, and economy. The electrode consists of a central metallic core surrounded by a layer of flux, which is protected by a metallic sheath.

Arc stability, is obtained by the use of a special flux. By a unique construction, this is included within the body of the electrode, being inclosed between the metallic core and the sheath. This prevents loss of the flux in transit or during welding and insures the presence of the correct quantity at the arc.

On account of the stability of the arc, it is easy to "strike" and to "hold" it. This makes it easier to make a good weld, because it permits the operative to concentrate his attention on other features of the welding operation. The training period of operatives is greatly reduced, and those who are already trained are able to do more and better work with less fatigue.

Rapid deposition is possible because the stable confined arc concentrates the heat at the point where it is needed, and hastens the rate of melting at the arc. The electrode can be used on either alternating- or direct-current systems.

The metal of the electrode can easily be made to penetrate effectually the metal being welded. The arc presents the minimum area of exposure to the surrounding air, thus restricting the opportunity for oxidation and nitrifi-

cation, which are most active around the borders of the arc. Sound, tough welds result from this restriction of atmospheric action. Moreover, the flux is a scavenger for oxygen and nitrogen and carries them out in a thin layer of slag. This slag further protects the deposited metal while it is cooling.

Maximum economy is obtained owing to the increased speed with which the weld is made, the more rapid deposition of metal and the fact that the operative can apply himself continuously to the work without fatigue. Other sources of economy are the reduction of power consumption, the smaller quantity of electrode metal necessary to make the required weld, and, most important of all, the better quality and greater reliability of the weld.

The welding electrode is supplied in diameters of  $\frac{3}{8}$ ,  $\frac{1}{2}$ ,  $\frac{5}{8}$  and  $\frac{3}{4}$  in. The  $\frac{1}{2}$ -in. size is furnished in 22-in. lengths and in approximately 200-lb. quantities on reels. All other sizes can be supplied in either 14-in. lengths or on reels containing approximately 200 lb. The short lengths are furnished in 50-lb. bundles covered with heavy burlap and securely fastened with a steel tape.

### Shock Absorber and Flexible Coupling Combined

Extremely simple in design is the new flexible coupling of the pin and bushing type introduced by the Terry Steam Turbine Co., of Hartford, Conn. The materials used in its construction have been selected with care and have demonstrated their fitness under actual working conditions.

The flanges are machined all over and are made from special composition steel forgings. Steel is used in preference to cast iron because of its greater uniformity and higher tensile strength. One of the most common faults of other couplings of this same general type is that they are constructed of cast iron. Castings are seldom uniform in density and free from blowholes. Lack of uniformity results in very low tensile strength, and makes it difficult and sometimes impossible to obtain correct balance. Both of these items are of major importance on relatively high speed, as well as on moderate speed apparatus where centrifugal force is an important factor.

The pins are also made of steel. To assure a smooth surface and long life, the cylindrical portion of the pins are hardened and ground. In this way the bushings are free to adjust themselves

under load and are prevented from transmitting end thrust. The pins are provided with screw heads and fibre washers which keep the bushings in their proper location within the driven flange. They may be removed readily with an ordinary wrench.

The bushings, which are the flexible medium, are made from a uniform grade of rubber that has demonstrated its ability to withstand hard usage. They are fastened securely to flanged steel spools which fully protect the ends and inner surface from wear. The rubber is ground to an exact outside diameter so that each bushing transmits its portion of the load. Since there is no chance of the bushings working into the space between the flanges they cannot become enlarged or transmit any axial motion.

#### BUSHINGS EASILY REPLACED

All parts of the coupling are made to limit gages, which assure accuracy and perfect interchangeability. Should the bushings need replacement, due to a large amount of misalignment, it easily can be done without any fitting whatsoever. The holes in the flanges are drilled and reamed with accurate jigs so that the pins are equally spaced and parallel to the axis of rotation.

Although every precaution is taken to insure uniformity of the flange forgings, very slight differences in density are unavoidable, therefore, the coupling is balanced after it has been finish machined. This prevents vibration set up by the coupling. Vibration would lead to wear and rapid deterioration of the connected apparatus or cause it to operate badly.

Aside from the excellency of the materials and the care used in the manufacture of the coupling, it possesses certain features which make it particularly desirable for all classes of service. Briefly its advantages are as follows: It compensates for both angular and off-center misalignment; it allows free end float of the connected shafts and will not transmit end thrusts; no special tools are required to disconnect it; by removing the pins, the shaft of either machine may be raised vertically without disturbing the other; it is easily and quickly checked for alignment; the driving flange is provided with a lip to protect operators; it does not depend on metal strips, rubbing surfaces, or any other unreliable medium for its flexibility; it requires no lubrication; it has a tendency to prevent the transmission of shocks; it acts as an insulator between the two machines, and, it is designed to

to operate in either direction of rotation.

The ratings which are assigned the flexible coupling are conservative and are based on many years of experience. Couplings are available in capacities up to 400 hp. per 100 r.p.m. In all cases it is rated so as to give maximum life and minimum wear. Generally speaking, it is stronger than the shafts on which it can be mounted.

The coupling is suitable for use with such equipment as steam turbines, electric motors and generators, fans, pumps, reduction gears, coal pulverizers, line shafting, etc.

### Expanded Metal Screening Withstands Vibration

A screen, which comes in stiff flat sheets and with edges clean-cut on both sides, has recently been developed by the Northwestern Expanded Metal Co., 407 S. Dearborn St., Chicago, Ill. This screening retains the strength of a steel plate without, however, its disadvantages of weight and bulk. Unlike most

Section of Expanded Metal Screening

There are no joints to become loose and thus cause the screening to unravel in this sheet of expanded metal.

guard fabrics it will not loosen up and sag even when subjected to a continual vibration and the mesh cannot unravel under handling or when being cut away. A blow or other accident may dent or possibly fracture a strand, but the injury is localized and will not spread or impair the general efficiency of the guard. Repairs can be made easily and inexpensively and openings cut at any point. The general rigidity of the expanded metal permits a wide spacing of supports.

#### SOON PAYS FOR ITSELF

A properly constructed, well-fitted guard made from this material will pay for itself in a surprisingly few years. On the other hand, a poorly built or flimsy guard is a constant expense, a nuisance, and also an added hazard, because it implies a protection which actually does not exist.

In the manufacture of this screening, sheets of medium open hearth steel are cut and expanded to form a fabric of diamond shaped meshes. The diamonds are formed by short sections of the original unsheared plate, and hence not dependent upon mechanical joints of any kind. The low carbon steel and cold rolling process of manufacture makes it a very tough, high elastic limit material.

Misalignment Corrected

A flexible coupling which does not create strains. Even the rubber bumpers are so designed that they cannot exert end thrust. The steel plates are accurately faced in order that they may be easily aligned.

Number 25

## Watching Our Opportunities

IN ENGLAND the coal market apparently is getting a bit restive because the conservative party was able to resume the reins of government. "Sooner or later," says a letter from a large English jobbing house to a list of American coal producers, "the new conservative government is going to get into trouble with our miners." If that time comes English coal production may be expected to be shut off again with consequent effect upon the importation of coal by England. This prospect adds another reason for the firm retention abroad of the trade representatives of the Department of Commerce. When there is any foreign economic disturbance either in prospect or in process this country needs to have a keen eye and ear on the spot.

## Pooling Brains and Experience

COAL COMPANIES, especially those in the anthracite region, do not arrange that their engineers and other workmen have sufficient opportunity to associate together and learn one from the other. One coal company official claims that the managers get together and interchange views on their various problems and go back to their offices and carry out their plans.

If this is all they do, it is easy to see why one company is highly developed along some lines of electrical application and a laggard along many others. When engineers themselves do not know what the other fellow is doing and cannot see where they themselves are progressive or unprogressive, how can they grasp the second-hand or third-hand information which may be transferred to them through official channels?

The electrical engineer has too hard a task today making his own president or general manager understand the problems pertinent to his own organization to hope to acquire information from another company by indirect methods.

A good live society is needed, and the coal companies themselves should encourage its formation.

## Fumbling at the Knot

COLLEGES and universities still fumble at the knot. If they want to train practical men, they must get men of practice in their college faculties. They must select electrical engineers who have worked at the bench, on the road, in the mine. They must get mining engineers who have designed and erected tipples as mining-company employees or as manufacturers' representatives. They must get as mechanical engineers men who can design and construct hoists, who can go into the factory or the boiler shop and take charge.

That requires money. That involves a reconstruction of staffs. Colleges are today too frequently merely bricks, marble, and stark intellect. Our industrial colleges should be built on the right kind of brains, on men who have an industrial knack, rather than an

intellectual afflatus. Too often college heads have gone the rounds looking for men at knockdown prices. They choose clever young men for fellowships it is true, who are good experimenters perhaps, but are failures as executives, designers and operating officials. Some day we may learn that the kind of talent that colleges must seek is talent that will sell, that commands a high price in the market.

The colleges must enter into competition with industry on equal terms, and when a college sees a man in the forefront of industrial progress it must offer him a salary that will lure him to the classroom. There is no other way of cutting the knot with which so many colleges are still fumbling. They get what they pay for, and the colleges do not grow. They become centers of research and of elementary education but not training schools for the higher walks of industry. Today young men must go into an apprenticeship in the shops and in the mines where they can be placed under talent of a kind which the colleges cannot attract because they are unwilling to pay for it. Let us hope that the collegiate atmosphere will come closer year by year to that of the mines, the mills and the factory and that of the millions given to educational institutions more will be spent in the endowment of adequate faculties. The glory of a college is not in its buildings but in its staff and in its students. Let that never be forgotten.

## What Makes for Stabilization?

STRANGE is the reasoning of those who would stabilize the coal industry. They tell us there are too many bituminous miners, and so there are; altogether too many. Those who question that statement are men who for their own personal advantage want to increase or at least maintain production. But there is too great a mining capacity already; so their contention is at fault.

What the stabilizers overlook is that the present wage is too high. If it were lower the excess of mine workers would automatically correct itself as it does in other industries. So long as wages are sustained by the same persons who desire to reduce the number of mine workers there cannot be any correction of the present situation. Where men can get \$7 to \$15 a day it is not likely that they will leave the industry permanently. Slow runs and short time may temporarily deplete an industry with such a wage rate—whether it will, is questionable—but it will not permanently reduce the number of men engaged in it. They will come back as soon as there is a demand for their services and even before they can be assured steady work. Lower wages will cure the excess and indeed little else will do it, except a restriction of the entrance of new blood into the industry by requiring previous experience in the mines. This latter course makes work in the mines a monopoly, and that surely is undesirable.

In most other industries, with the notable exception

of railroading, the wage is determined by supply and demand. Consequently when the demand is low, the supply falls off. In the coal industry when times have been bad and work has been irregular, the wage is raised by a fiat of the Administration and of the public. Thus the miner is compensated for his past idle time, and the wage is pushed further up above the normal rate; this is crystallized by an agreement. More men enter the industry. Business declines, and the miner soon suffers from short time.

When times improve he asks for more wages to compensate for the short working hours of a previous year. Again he gets an increase, and again more men enter the industry. It is a vicious circle. We get nowhere by adopting the plan of giving a yearly wage to the miner. We make it necessary to pay ever more and more. It makes more idleness, more discontent. The wage that is given makes a higher wage more necessary. The path we are treading leads ever to a more aggravated condition of a deplorable evil.

More men means large mine capacity and more mines; so that the other evil, too many mines, follows in the same train. Figure the miner's wage per day and not per year, and conditions will right themselves. An uneconomic theory is bearing the industry fast to the rocks of over-manning and overdevelopment, and the stabilizers should realize that fact. But politics makes it necessary to talk stabilization and high wages in the same breath, and who will say that the one does not negative the other? The stabilizers do not know whether they are singing bass or soprano.

### Line Up with the Best

WHAT a confusing babel of sounds one can expect to hear when the United Mine Workers' officials get together to plan legislation to curtail the use of electricity in the mines, as they have declared it their purpose to do at their recent meeting in Harrisburg.

In the anthracite region many companies do not know what the others are doing, electrically. One large company may pride itself upon its power plants and extensive use of electricity, yet be far behind another and a smaller company that has put more brains into its work. Each company has relied too much on its own ability to think out and devise new plans, and as a result is in some ways far behind others in the safe use of electricity.

The electrical hazards found at some mines are real and many. There are breakers which have no electric lights but instead use open-flame oil lamps with their ever-present fire hazard. Well-lighted shaft bottoms greet you in some mines whereas others are dark and damp death traps. At some mines only 440-volt motors are used, but they are installed in such a manner that they are more dangerous than the 2,300-volt motors at another mine.

Crooked and twisted trolley wire supported on old-type hangers which leak and cause the trolley wire to sputter sparks on powder cans, hay and feed have taught some companies serious lessons. Open-type circuit breakers instead of closed types have caused dangerous flashes. Sectionalizing trolley switches left closed during the night have been responsible for mine fires. Leakage currents in hoisting cables and pipes have shocked the workmen.

In every anthracite mine some of these hazards have been guarded against, but others have made no provision against them. Despite the need for concerted

effort the coal companies have never met to formulate definite practices that would assure safety.

Perhaps the greatest difficulty of all lies in the fact that the mine foreman and not the electrical engineer supervises the work of the men in the mines who maintain, operate and repair the electrical equipment.

### Your Place in the Coal Industry

A CERTAIN large operator had several mines in an excellent coal seam and under that almost unequalled bed lay two or three more beds of coal, above the average, it is true, but not equal to the first. Did he mine these latter? Not at all. He mined out the best coal and looked around for more.

He thought that he had found a good deposit and opened a mine in it, spending a million dollars before he got a single pound of coal. It will be remembered that in those earlier days a cool million was regarded as a tremendous sum. He found, however, that the coal he got from his new venture was fast injuring his reputation. It was altogether too volatile and had too much ash. He could have continued to sell it for what it was, a coal of medium quality, but he could not prevent it from lowering his standing in the market. Even had he organized another company to work the coal and sell it, there always would have been the assurance that the story would leak out that he was the principal owner, and the sale of it would injure the excellent reputation he had acquired of marketing nothing but the best, so he sold the mine to other operators who could well afford to ship such coal, seeing that they were already producers of coal of only medium quality and traded in a less discriminating market.

About the same time he purchased another field having a seam of excellent coal. Above the bed he bought was another containing a coal of equally low volatile content, but it had more sulphur. He did not buy that bed, however. He was determined to mine nothing but the best.

In time the coal seam in the area in which he first operated was exhausted, and he leased out the other seams below it. These seams had fairly good coal, as has been stated, but he would not work them. They would have injured his reputation. He concentrated his efforts on the good seam in the new area he had purchased and developed. Now he is making an analysis survey of this good seam so that he can mine the best of it, and leave the rest.

The time may come when he will have to work what he is rejecting. Some time he may have to mine this less desirable coal or perhaps may have to establish himself where the coal is still lower in heating value. But he will maintain his standing by mining the best that is obtainable. To do otherwise will mean that he will be obliged to class himself with those who are producers of only fairly good coal. He may wash it and table it, but it is likely that it will never be as good as that which he is now selling. However, he will see to it that it is still the best on the market.

The moral is short and pithy. Do not go to the market with all kinds of coal for all comers. Specialize on one kind of coal with preference for the best. Some of the present consolidations may not have been formed with this simple rule in mind. If a man is known to have a good and an only medium coal, his customers will be wary of buying from him, for they will hear on one side of his higher price and on the other side that his coal is not of first quality. Standardize, therefore, standardize!

# Machine Loads 377 Tons Into 2-Ton Cars In 8 Hours From Room Workings

*Traversing a Crosscut*

**Average Production of Machine for a Month, 289 Tons—Crosscut Turnouts and Two Car-Shifting Locomotives Facilitate Loading—Big Car Advantageous—Pillar Coal Is Being Loaded Mechanically**

BY ALPHONSE F. BROSKY  
Assistant Editor, *Coal Age*,  
Pittsburgh, Pa.

**T**HAT LOADING machines can be applied successfully to room-and-pillar mining is being convincingly demonstrated at a mine in northern West Virginia where substantial increases in the daily output per man employed and important savings in the cost of production have been made. Even so, what is being accomplished is only of an experimental nature intended to serve as a guide in the planning of future mechanized developments.

Impressed with the possibilities of saving in the labor of coal loading by the use of machines, the Pittsburgh & Erie Coal Co. procured an Oldroyd loading machine for use in its Sumner No. 2 operation. This mine is located at Braznell in the Monongahela district of Pennsylvania. What the company desired to ascertain was the exact degree to which the theoretical possibilities of loading machines could be realized.

This loader was put to work in the thick Pittsburgh bed under conditions that could not by any means be considered favorable. Sumner No. 2 is an old and almost exhausted operation. No block of coal of adequate size for experiments in mechanical loading could be found in it, and for this reason, tests of the machine's loading ability were somewhat desultory and inconclusive. It was soon discovered, however, that even in the Pittsburgh bed, with its troublesome draw-slate, loading machines possess more than mythical advantages. Upon one occasion the machine succeeded, during an 8-hr. shift, in loading 250 tons of coal into mine cars of 1.6 tons capacity.

## NEW AND MORE PROMISING FIELD PROVIDED

Desiring to continue the experiments where they were discontinued, but under conditions similar to those prevailing at the Sumner No. 2 operation, the Pittsburgh & Erie Coal Co. closed negotiations for the privilege of mechanically loading coal in a small section of the Robert mine near Clarksburg, W. Va., this mine being owned by the New Superior Coal & Coke Co. Incidentally it may be said that during the recent war an attempt was made to produce coal in this property

Although the loading machine shown in the headpiece is 45 ft. long it is built in three sections or segments and as may be judged from the illustration no difficulty is experienced in taking it through crosscuts. These passages, however, are driven on a 45-deg. angle and the track curves have 35-ft. radii.

by stripping. This, however, failed because the cover, which ranged from 40 to 75 ft., was too thick for ordinary stripping equipment.

Machine loading in the Robert mine under the supervision of T. F. Whalen, general superintendent of the Pittsburgh & Erie Coal Co., began about the middle of July of the present year. Some time was required, however, to prepare the sections and make the changes necessary for the introduction of machine methods, and it was not until the latter part of August that the work approached the production stage.

During twenty-four 8-hr. shifts worked in September, one machine loaded 6,058 tons, or an average of 252 tons per day. Twenty-four men including a mine foreman, mined, shot, loaded and transported all this coal from the face to the railroad car. The daily output per man employed was thus 10½ tons. The results achieved during 17 working days of October, however, were far better. During this month the same number of men with one loading machine produced an average of 289 tons per shift, or a daily output per man of 12 tons. Even this performance is scarcely indicative of the machine's possibilities, for on one day the crew mechanically loaded 377 tons of coal.

The Oldroyd machine used at this plant is 42 ft. long and weighs 22 tons. Although its over-all height is 54 in., it can operate in a 5-ft. coal bed. It travels upon, and works from, the mine track, its massiveness of construction enabling it to push itself under loosened coal and thus to break out hanging shots. The machine is not only powerful, but it has also a reach that enables it to gather in the coal from the entire face without leaving the track. It is equipped with three conveyors, the middle one being fixed to the body, while the front and rear sections swing in either direction, horizontally as well as vertically. Both motions can be made simultaneously.

## TWO CUTTER CHAINS DRIVE LOADING HEAD

Coal is fed into the forward conveyor by means of a revolving dipper. This consists of a roll of small diameter on which are cast two plate paddles spaced 180 deg. apart. This feeding device is driven by two cutter chains provided with pick bits which cut a path in the coal pile for the bearings as the machine

advances. The main body of the loader is supported by two sets of swivel trucks which enable it to round curves with ease.

Five motors are utilized to give independent yet correlated movement to the various machine elements. As far as possible, chain drives have been eliminated, transmission being made by means of gears and worms.

Two men operate the machine. One controls its forward movement, the starting and stopping of the dipper and the swinging of the forward boom. The other starts and stops all three conveyors and controls the position of the rear boom. This two-man control is analogous to that of the ordinary steam shovel.

The layout of the Robert mine where this machine is employed is shown in Fig. 4. Rooms are driven 400 ft. long and 20 ft. wide on 30-ft. centers. They are necked on a 45-deg. angle in order to provide a turnout of greater radius than is normally provided for gathering locomotives. This is necessary to facilitate movement of the loading machine. For the same reason crosscuts are turned on a 45-deg. angle in one direction only. The inby crosscut, placed at a convenient distance from the room faces, is tracked to

Fig. 1—Loading Machine Used in Robert Mine

In this illustration the loader is in working position at the end of a coal pile. Inasmuch as this machine operates from a track the span of unsupported roof is only slightly greater than the depth of cut plus the track gage.

expedite haulage and to permit of the movement of the loading machine from one room to another without the necessity of traversing the butt entry. As a matter of fact, only one of the crosscut turnouts is of sufficient radius to enable the loading machine to pass between the rooms thus connected. It is the intention to install turnouts of 30- to 35-ft. radius equipped with a No. 2 frog.

The track is laid up the center of the rooms. On each side of this room track is set a row of props on 5-ft. centers. The coal is cut to a depth of 8½ ft. at a height of 6½ ft. above the floor, leaving 1 ft. of top coal to protect the roof. Fig. 6 shows a circular cut being executed by an Oldroyd Universal machine which also shears the coal in the center of the face. One long shothole on either side of the shearing cut and one short hole in each rib are employed to break down the coal.

#### HEAVY SHOOTING ASSURES EASY LOADING

In this mine, shotholes are charged rather heavily for two reasons: First, the coal on reaching the outside must be carried to a railroad siding on the farther bank of a stream by an aerial tramway, the buckets of which are too small to hold large lumps. Second, the circular cut made by the mining machine in a width of 20 ft. leaves two tight corners, which require two light rib shots.

Satisfactory shooting for mechanical loading presents problems all its own. In this particular mine,

Fig. 2—Breaking Down a Hanging Shot

Rugged construction and massive weight enable the machine to disrupt masses of standing coal as shown. Though this process is slower than shoveling loose coal from the mine floor it affords a coarser product. The hand shoveler seen in this illustration saves the machine much time by gathering up stray pieces of coal that the machine could reclaim only with difficulty.

as has been stated, the coal is undercut and center sheared to a depth of about 8½ ft. The two light rib shots already mentioned are sufficient to bring the coal away from the sides and roof, but they do not break and roll it out on the floor. They result rather in a true hanging shot, most of the coal remaining in two blocks upon either side of the shear cut. These are broken away from the roof and show some evidence of a slight separation and movement along the cleavage planes.

An attempt to load out these blocks shows that this apparent shattering does not extend throughout the entire mass, as certain portions stubbornly resist, although they finally succumb to the powerful action of the revolving dipper. This shooting, however, gives a product with a low percentage of slack, the quantity of coal less than ¾ in. in size making a proportion of the whole product from 7 to 10 per cent less than that obtained with hand loading. Center shearing and light shooting, although not extensively practiced, has many strong advocates among present-day mine managers. Lumps weighing almost 200 lb. each are successfully handled by this machine. In fact, the size of the individual pieces loaded appears to be limited only by the width of the dipper and the conveyors.

The method of handling cars in the Robert mine is plainly shown in Fig. 4. A trip of empties is stored in room 4, adjacent to room 5 where coal is being loaded. A turnout connecting the tracks in adjoining

Fig. 3—Cutter Chain Driving Feeding Device

Pick bits carried by this chain clear a passage in the coal pile for the conveyor bearings. This chain, together with a similar one on the opposite side of the machine, rotates the revolving dipper on the gathering head.

rooms is laid in the crosscut most conveniently located to the face. This facilitates the storage of a trip of empties inby and provides clearance beyond the turnout switch in the room being loaded out. In order to accomplish its purpose most effectively, such a crosscut turnout should be from 75 to 150 ft. from the working face.

#### TWO LOCOMOTIVES CHANGE CARS QUICKLY

Two 5-ton storage-battery locomotives constantly attend the loading machine. Barring delays arising from changing trips, from faulty track or rolling stock, the only time consumed in changing cars is that required by a loaded car in clearing the turnout in the crosscut, or that necessary to push an empty from the turnout to the loading machine. The ease with which cars may be changed may be traced in rooms 4 and 5 of Fig. 4.

The motor A with a loaded car clears the turnout in room 5 on its way to the butt entry where the loaded cars are stored. Motor B pushes an empty car to the loading machine. While this is being filled, motor A

uncouples its loaded car on the entry in the clear of room 4, goes into this room, couples onto an empty and waits in the crosscut for its turn at the machine. Aside from a short backswitch while dropping a loaded car on the entry and coupling to an empty car in the room, the two motors move in closed circuits.

I timed with a stop watch the performance of the loading machine in rooms 4 to 7 inclusive (see Fig. 4). My observations extended from 9:04 a.m., when loading began in room 4, until noon, when work ceased after nine mine cars had been loaded in room 7. They thus extended over a period of 176 min. In totaling the stop-watch readings a minus error of 1½ min. was noted. This arose from protracted periods being read in whole minutes and not in minutes and seconds. The error amounts to less than 1 per cent and consequently may be neglected.

Readings showing the operation of the machine, loading periods, time necessary to shift cars and time lost in rooms 4 to 7 respectively, are shown in Tables I to IV. Five minutes were taken to move the machine from room 3 to room 4, and an equal length of time was consumed in making ready for the machine. In room 4, 19 cars containing a total of 43 tons were loaded in 40 minutes. Five minutes was consumed in moving the loading machine to the face of room 5, a distance of 740 ft., and 6 min. was consumed in making ready for loading operations. In this room

Fig. 4—Room Layout in the Robert Mine

When machine loading was started in this mine it was thought that room coal could be loaded much faster than pillar coal. Experience has shown that there is little difference in the time required to produce coal from either of these two sources and consequently instead of driving 20-ft. rooms on 30-ft. centers it is the intention in the future to make the pillar thickness equal to the depth of at least two cuts.

eighteen cars containing 40 tons of coal were loaded in a period of 34 min. The loading machine was moved to the face of room 6, a distance of 700 ft. in 6 min., and again 5 min. was required in making ready for loading. Here eighteen cars containing 40 tons were

loaded in a total time of 34 min., the loading machine was then moved to the face of room 7, a distance of 500 ft. in 5 min. In 9 min. the machine was made ready for loading operations in this room, and in 22 min. thereafter nine cars containing 20 tons of coal had been loaded.

"Making ready" included inspection, minor adjustments and lubrication of the loading machine, also repairing track when necessary and sumping into position. Coal in the face of room 6 was shot down in better shape for machine loading than that in any other room; that in the face of room 7 was in the worst shape. Because the face of room 7 was not sufficiently shot, the rate of loading was lower by over 30 per cent, than in room 6.

The wisdom of using two locomotives is readily dis-

Table IV—Time Study of Loading Machine in Room 7

cernible from an inspection of Tables I to IV inclusive. Reading down the car-shifting column in these tables it will be noted that the time consumed in changing cars generally varies from 15 to 35 sec., depending upon the distance of the turnout from the face. In a few cases as much as 70 sec. was consumed in this operation. Naturally when trips were changed more time was required. Long periods consumed in car shifting in any one table arose from the use of old mine cars that were in poor repair. Rolling stock in proper condition and well-kept track should make it possible to rely on being able to change cars in 30 sec.

In Table V are shown the totals for each phase of the loading operation for each room as well as a grand total for all rooms. From it the following facts may be derived: Actual loading of cars consumed 40.6 per cent of the total time observed; shifting took 20.6 per cent; moving the machine required 12 per cent; making ready, 14.2 per cent; the time lost was 12.6

Fig. 6—Starting a Cut in a Room

The top is cut and the center sheared with a Universal machine at this mine. About 1 ft. of top coal is left up to protect the roof. Center shearing makes more bug dust but gives more lump coal per room cut, than could be obtained without it.

per cent of the whole time. During 176 min. 64 cars containing 144 tons of coal were loaded at the rate of 39.1 tons per hour. This rate of production if continued throughout a full shift, would yield an output of almost 400 tons. It is not maintained throughout the working day, because the mine cars are old and not fitted for the work they are called upon to perform. They were constructed originally to hold 1½ tons, but by the addition of sideboards their capacity has been increased to 2½ tons. Another obstacle that interferes

Table V—Totals of Tables I to IV Inclusive

with the attainment of this 400-ton output is the aerial tramway shown in one of the accompanying illustrations which transports the coal from the dump to the railroad cars. This means of transportation has a maximum capacity of 375 tons in 8 hr. It is responsible for much of the time lost.

Table VI, covering seventeen working days in

FIG. 5

#### "A Slab Cut"

When track is maintained along the full length of a slab cut the coal rolls out over it making the work of the shoveling machine difficult. The present practice is to add short sections to the track as the machine advances, thus allowing the revolving dipper to work on an unobstructed bottom. The operation of the machine is thus facilitated, and doubtless some degradation of the coal also is avoided.

Table VI—Summarized Record for Seventeen Working Days in October

Working Day	Tonnage Produced	Hours Worked	Hours Delayed	Remarks
1	215	5	3	Repairing loader

October, lists the tonnages obtained, hours worked, time lost and the reasons therefor. On an average day during this period 16½ per cent of the working time was lost because of miscellaneous delays arising from equipment. Less than one-fourth of this loss was occasioned by trouble with the loading machine.

The loading-machine crew consists of three men, two runners and a third man stationed beside the forward

cut. Of course, if this coal contains a large quantity of small pieces it would be as hazardous to shoot the coal over it as it is to fire a shot over a pile of bug dust.

It should be remembered that the ratio of operating time to tonnage obtained is the chief factor governing the efficiency of a loading machine. Because a tonnage equivalent to the capacity of the machine during a period of at least five minutes is lost in gathering stray lumps, two men with shovels might be employed profitably to relieve the machine of this duty. It is probable that no loading machine will ever be built that will perform all the functions of a human loader, or be sufficiently flexible to match the co-ordination of man's brains and muscles. All that any machine can ever do is to approach this ideal. The deficiency of the coal loader must be made up by muscular effort.

#### TWENTY-FOUR MEN MINE 289 TONS DAILY

The following men were employed both inside and outside the Robert mine in order to produce the tonnage shown in Table VI: One foreman, two loading-machine runners, one loading-machine helper, two motormen, one trip rider, two cutters, four tracklayers, two timbermen, one blacksmith, four tippie men, one elec-

FIG. 7

#### Room Face

This is the face as it appears after the machine has completed its loading. It is unprofitable to employ the machine to clean up the last bit of coal in a room. The last two cars produced from this place took as much time to load as did the first seven. What coal remains at the face will be loaded out with that from the next cut.

conveyor who shovels up coal missed by the machine. Occasionally a fourth man for cleaning up would be desirable, as the time lost in operating the loading machine at a slow rate when gathering up stray lumps of coal, might be more profitably spent at points where the coal is deeply bedded. An inspection of Tables I to VI will show this fact conclusively.

Reading down the car-loading column in each of these tables, it will be noted that mine cars (capacity 2½ tons) were loaded in as short a time as 30 sec. Nevertheless, the loading period per car attains a maximum of 250 sec. It is true that a portion of this excess time is consumed by the loading machine in dislodging tight coal, but more than half of it results from the necessity of maneuvering the machine about in order to gather up sparsely strewn lumps. This especially is noticeable when loading the last two or three cars from a room. Even then a small quantity of coal is left for recovery with the next cut. Because of the long time necessary for loading the last few tons of coal from a room, it would appear advisable to leave much of this material for recovery with the next

trician, two shotfirers and one watchman. These twenty-four hands loaded an average of 289 tons per working day during October, or 12 tons per man. Of course, no development was attempted when rooms were being worked. Consequently the output was high as compared with what might be expected if both rooms and headings were being driven simultaneously. The additional labor necessary for development work in this mine, would not lower the daily output per man to less than 10 tons. With a 5-ton car, the daily tonnage per man employed in mining operations would probably range from 10 to 15 tons.

The advantages of a large mine car when used in conjunction with mechanical loading are apparent to the officials of this mine. General Superintendent Whalen intends to adopt a 5-ton car with a 48-in. track gage as standard for a new mechanically operated mine that his company contemplates opening. With cars of this capacity, the Oldroyd machine ought to load 500 tons in 8 hr. under conditions similar to those existing in the Robert mine and with the same number of employees. To produce 500 tons, the coal from twelve

FIG. 8

### Tipple and Tramway

This method of transporting the coal from the dump to the railroad car already is beginning to limit the capacity of the loading machine, for as at present operated it cannot carry more than 375 tons in 8 hr. Furthermore it cannot handle large lumps.

room cuts would have to be loaded into 100 mine cars.

Table V shows that a 2½-ton car may be loaded in an average time of 66 sec. At this rate of loading, a 5-ton car could be filled in 138 sec. or 100 cars in 13,800 sec. This represents 48 per cent of an 8-hr. day. It is calculated also from an analysis of the facts set forth in Table V, that about 11 per cent of an 8-hr. day would be spent in shifting cars, and not over 12 per cent in moving the machine, leaving 29 per cent of the time for miscellaneous delays. This would appear to be an ample allowance.

Little success has been reported thus far in drawing pillars with mining machines. Possibly the slow progress attained in this phase of mining operations is attributable to a lack of persistence and official supervision in making the necessary experiments. There is little doubt, however, but that some day pillars will be drawn thus, and inasmuch as they can be removed

much more rapidly with loading machines than by hand, the retreat will be rapid, lessening the danger from falling roof and rendering pillar extraction safer than it is today. It is possible, also, that less slate will have to be handled.

### PILLAR COAL MUST BE SLABBED

It is highly probable that whatever method of mining is adopted, the loading of pillar coal by machine will involve slabbing. Several reasons dictate the adoption of this method. In the first place, a slab cut produces more coal than any single cut made in driving through a pillar, leaving one or more stumps that must be recovered before the next cut is started. Consequently a slab cut expedites recovery and assures safety. It also eliminates sharp curves in the track and provides a more suitable working place for the loading machine.

Pillars are being extracted by loading machine in the Robert mine. The results thus far achieved have been highly successful, and the work has progressed to such a point as to prove that the practice is entirely feasible. Thus Mr. Whalen states: "This work has proceeded without any difficulty whatever and the machine has never been forced to retreat because of unfavorable roof conditions. We feel that we have already demonstrated conclusively that it is possible to draw ribs with this type of loading machine in mines where what might be termed a medium roof prevails."

Though at the initiation of its experiments the company was hopeful of recovering pillars by mechanical loading, it anticipated that greater difficulty would be encountered in loading pillar coal than in loading that obtained from room faces. Accordingly, rooms were driven wide on as narrow centers as the roof would allow. Twenty-foot rooms on 30-ft. centers were therefore adopted as standard, 10 ft. of pillar being taken as the minimum width that safely would hold the roof.

The withdrawal of these pillars is illustrated at A in Fig. 9. The track is first shifted as near to the rib as possible, so as to facilitate the work of both the cutting and loading machines, which operate from it. The pillars are mined by slab cuts on the inby end. The length of such cuts varies from 10 to 30 ft., depending upon the condition of the roof. An 8½-ft. cut leaves a rib about 1½ ft. thick, which, though frequently shattered by shooting and roof pressure, generally requires some pick mining. Some hand shoveling also is necessary in order to place the coal from this rib within reach of the loading machine. The closed end of a pillar cut is sumped on a 45-deg. angle to facilitate machine loading at this point.

Fig. 9—Recovering Pillars by Machine Loading

Pillars are drawn by slabbing without stump protection. The method now used is shown at A. The 10-ft. pillars are slabbbed to a depth of 8½ ft. the remaining coal being recovered by pick mining. The probable future method of pillar drawing is shown at B. The pillar width will be increased to 14 ft. providing for two 7-ft. slabbing cuts. The first of these will be recovered in a manner similar to that now employed, but the loading of the second will require a curve in the track that will enable the machine to take a position close to the cut.

No track is laid along that portion of the pillar being mined. As the cut is loaded out and the machine moves forward, short rail sections are added to the track. This enables the dipper of the machine to load on an unobstructed bottom.

A row of props is set along the track. Against these, and flanking a slab cut, three or four steel plates are placed on edge, thus confining the coal rolled out from the cut in shooting. A heavy crossbar, and two strong posts are erected abreast of the gob end of a retreating pillar to assist the props in holding the drawslate and other rock immediately overlying the coal.

In fifteen working days the pillar between rooms 1 and 2 (see Fig. 4) was shortened 230 ft.; that between rooms 2 and 3, was drawn back 120 ft.; that between rooms 3 and 4 was shortened 110 ft.; and that between rooms 4 and 5 was retreated 30 ft. This recovery

is equivalent to that of a 10-ft. pillar having an aggregate length of 490 ft., yielding about 1,370 tons. Only one-fourth to one-third of the time required by hand methods is necessary for drawing pillars by machine. As a result, less pressure is observed on the ends of the pillars nearest the gob, and working conditions generally are far safer than in ordinary pillar sections.

Inasmuch as this company has proved that pillar coal can be mined by a loading machine about as conveniently as room coal, it now believes that 20-ft. rooms should be driven on centers of 34 ft. or wider. If the 14-ft. room pillar thus formed could be mined through by two slab cuts each having a depth of 7 ft., the first cut would be mined out in the same manner as that shown at A in Fig. 9. In order to bring both cutting and loading machines within reach of that portion of the pillar taken in the second cut, it will be necessary to curve the track inward as shown at B in this figure.

## Great Britain Revises Its Mine Electrical Rules

Cannot Use Electricity Without Permit—May Transmit Current Above 650 Volts but When Used Must Be Stepped Down Below That Voltage

BY C. H. S. TUPHOLME  
London, England

**N**EW regulations have just been issued by the Minister for Mines governing the use of electricity in coal mines, the main features of which may be summarized with advantage.

If an operator intends to introduce any electrical equipment into his mine, or into any ventilating district in his mine, or wishes to re-introduce electricity into a shaft where the use of electricity has previously been ordered out, he must give notice in writing to the government inspector of the district. If this inspector does not object in writing within a month, then the operator may regard his silence as consent, and may go ahead with his plans. The only exceptions to this are telephones and signaling apparatus.

Every coal-mine operator is obliged during January of every year to make out a return of all his electrical equipment, giving details of its size and type. He is also obliged to keep up to date a scale plan of the mine showing all the fixed electrical apparatus. This plan must be produced on the demand of an inspector.

The usual notices, constructed of durable material, must be exhibited where necessary, that is, prohibiting unauthorized individuals from handling electrical apparatus, giving directions in case of fire, directing the treatment of victims of electric shock, and instructing as to the manner by which communication can be established with a qualified individual in charge of the main switch of the underground electric system. The last notice must be on view at the shaft bottom.

### SECONDARY LIGHTING IN HAZARDOUS PLACES

In locations lighted by electricity, where failure of the light might lead to danger, some type of lamp must be kept continuously burning; there must be an efficient telephonic system between the main switchgear and the main distributing center in the pit; and fire buckets filled with sand must be kept wherever there is any electrical apparatus.

If equipment such as transformers or switchgear are likely to be damaged they must be kept in a separate compartment which must be constructed of fireproof material and must also always be kept dry and free from obstruction.

Every part of the electrical system in the mine must be efficiently insulated, except that (1) the neutral point of a polyphase system may be grounded at one point only, (2) the mid-voltage point of any system, other than a concentric system, may be grounded at one point only, and (3) the outer conductor of a concentric system must be grounded. All generators, transformers and motors, including the portable type, must be connected to a grounding system at the surface of the mine. No conductor of a grounding system may be less than 0.022 sq.in. cross-sectional area.

Where electricity is distributed at a higher potential than 650 volts, it must not be used without being stepped down to below 650 volts and in fact to 250 volts, except in fixed equipment in which the high-pressure parts are stationary. Alternating-current motors smaller than 20 hp. must be supplied with energy through a transformer which will step the potential down to less than 650 volts.

Switchgear and all electrical connections must be rugged enough to withstand rough usage, must be protected against the lodgment of dust on or near live parts, and must be so constructed that there is no open sparking.

### NO SWITCH ALLOWED ON OUTER CONDUCTOR

If a concentric cable is used no switch or fuse may be placed in the outer conductor, unless it is a reversing switch installed where the current is being used. Switches or fuses may, however, be used to break connection with generators or transformers, providing there is no interference with the grounding system of the outer conductor.

All cables, except those for portable apparatus, must be insulated and supported at intervals to protect them from damage. Where the roadway is used for mechanical haulage or where there is any explosion hazard concentric cables, two-core or multi-core cables must be protected by a metallic covering if the potential exceeds 250 volts.

Provided a direct-current system is used not exceeding 650 volts, two single-core cables protected by metal may be used for any circuit, provided the metal cover-

ings are bonded together by ground wires not farther than 100 ft. apart.

An operator working an electrically-driven coal-cutter must not leave the machine while it is working, and he must, before leaving the working place, satisfy himself that the current is cut off from the flexible trailing cable which supplies the coal-cutter.

Current from lighting or power circuits must not be used for firing shots, and cables used for this purpose must not be allowed to come into contact with other conductors.

Haulage by electric locomotives on the overhead wire system is prohibited in any coal mine. Storage-battery locomotives may be used only when permission in writing has first been obtained from the Board of Trade.

Every mine where electricity is used must employ a properly qualified electrical engineer, and if this official is absent for more than one day, the manager must appoint in writing an efficient substitute. The electrician must maintain a daily log book on the prescribed sheets, and this book must be produced on the demand of an inspector.

## Boiler Economies for Coal Men Exhibited at Power Show

Settings, Valves and Meters Being Devised to Meet Trying Demands of Modern Economical High-Temperature Operation

THOSE who visited the Power Show held in New York during the week of Dec. 1 to 6, in conjunction with the annual meeting of the American Society of Mechanical Engineers, could scarcely fail to notice how greatly the number of exhibitors of certain products has increased in recent years. The general quality of the products exhibited also apparently had shown vast improvement.

Perhaps the number and diversity of three items or types of equipment impressed even the casual visitor more quickly than any others. First, a wide variety of refractories were shown. These included many kinds of firebrick in both regular and special shapes as well as insulating brick to be incorporated in the boiler or furnace walls to prevent radiation, also baffle brick, and fireclays and cements of many types. Many such refractories have doubtless been developed to meet the exacting requirements imposed by high boiler overloads as well as the extreme temperatures obtainable by the use of powdered fuel.

### VALVES AND FITTINGS IMPROVED

Pipe valves and fittings also were much in evidence. Only a few years ago extra-heavy cast-iron fittings were considered amply strong for practically any power plant. At this show were exhibited not only steel-casting valves and fittings but also those made from steel forgings. High pressures and superheats demand a type of fitting and even a variety of pipe joint that was totally unnecessary less than a score of years ago.

The third class of power plant apparatus to impress the visitor by its diversity was what might be termed measuring or indicating equipment. In this type might be enumerated, pressure and vacuum gages, high- and low-water alarms, water gages, try cocks, thermometers, hydrometers, psychrometers, pyrometers, draft gages, flue-gas indicating and analyzing apparatus, air meters,

steam meters, water meters and similar devices in vast and formidable array.

Exhibitions of this kind as a rule furnish a fairly reliable index of the progress of the industry, trade, calling or profession represented. Power generation today is an exact science and the modern steam boiler is capable of scientific control and manipulation. The chief requisite for firing a boiler was once considered to be a strong back. Today the actual firing is done by a stoker or, in the case of powdered coal, by an air blast. The fireman must, however, preserve the balance between rate of fuel consumption and load, supply the air requisite for combustion but admit as small an excess as possible, regulate the draft, and otherwise so control the fire as to obtain uniformly the best results possible.

### SCIENTIFIC KNOWLEDGE NECESSARY

This cannot be done blindly or by guess—each move and adjustment must be predicated upon exact scientific knowledge or no exact scientific results will be achieved. He will be most successful as a power producer, who, by means of scientific instruments ascertains the conditions existing in the boilers and furnaces intrusted to his care and then modulates these conditions to suit the load to be carried and in such manner that the maximum proportion of the heat energy contained in the fuel is transformed into useful work.

At the mines coal is less valuable than it is anywhere else except in the ground. Refinements in plant equipment and operation that might be fully justified at an industrial establishment located some distance from the point of fuel origin may not find economic justification at the mine mouth. Nevertheless, if the coal-producing companies generally at their plants engaged such men and installed such equipment for obtaining low-cost energy, as sound economics fully warrant, their costs for coal produced, in at least many cases, would be lessened appreciably. In other cases, being able to generate their own energy cheaper than they could buy it, they would be enabled to maintain their own plants and thus would be freed from the exasperation and expense arising from the more or less frequent failures of power which companies sustain who purchase their energy from a central station.

VACUUM CLEANER FOR SAMPLING COAL DUST—Experiments to determine the feasibility of sampling coal-dust accumulations in mines by means of some method of vacuum cleaning are being conducted by the Pittsburgh Station of the U. S. Bureau of Mines. To separate the dust from the air, canton flannel is used in the domestic vacuum cleaner. Canton flannel allows too much dust to escape, and alundum filters are regarded as more efficient. Tests will be made by the Bureau of Mines to determine how much dust passes filters of the latter type.

SAFETY ASSOCIATION GROWS RAPIDLY—There are now 94 local safety chapters of the Joseph A. Holmes Safety Association located in the different mining districts of the country. Each of these local chapters has a safety director who has been specially trained in the U. S. Bureau of Mines methods of teaching mine rescue and first aid. These safety directors instruct classes of miners, thus supplementing the training work conducted by the Safety Service of the U. S. Bureau of Mines.

## Pittsburgh Coal Co. Evolves Dust Distributor

Nozzle Projects Dust to All Surfaces in Proper Proportion—Mechanical Mule Draws Train at Suitable Speed for Complete Distribution in One Application

BY ALPHONSE F. BROSKY  
Assistant Editor, *Coal Age*,  
Pittsburgh, Pa.

FOR MANY months the Pittsburgh Coal Co. has been building rock-dust distributors in its central repair shop and simultaneously rock dusting its mines. Seven of its mines have already received dust treatment, and the work will be extended to others as the expediency for doing so becomes apparent. One machine after another has been built, tried out and torn down for alteration, only to give way eventually to some other type that proved itself superior. Numerous tests were made in the yard surrounding the company's Library shop, in the progress of which tons of rock dust were blown into the atmosphere. A satisfactory arrangement for feeding the rock dust uniformly and continuously from a hopper to the blower tube and discharge nozzle was devised only after numerous changes had been made. Nozzles of many kinds were tried before the type now being used was accepted.

The Pittsburgh Coal Co. now has a rock-dust distributor that not only lays dust so that it will lodge uniformly on the roof, ribs and floor, but does its work rapidly and with a minimum of labor. Even so, the company does not claim to have a perfect machine, though the present device has proved satisfactory.

On Nov. 24 the machine was moved from Montour No. 4 to the Mansfield mine where it was put to work that night without much advance preparation. In six hours it distributed 203 sacks of limestone dust, each weighing 80 lb., along 7,000 lin. ft. of entry, laying 2.3

lb. per lin. ft. It is capable of discharging 1,500 lb. of dust in 12 minutes of continuous running. The dust train, composed of the machine and two mine cars filled with sacks of rock dust and pulled by a small, special-type, low speed locomotive, was manned by two men.

The rock-dust distributor is shown in Fig. 1. It is protected by pending patents in the names of three of the company's mechanical men who are responsible for its design. Its overall height above the rail is 40 in. From an open-top hopper, having a capacity of 18 sacks or about 1,500 lb., rock dust is fed to the blower tube by a 4-in. worm or screw conveyor located in the hopper bottom and having a 45-deg. pitch. Half of its length is incased in a tube connecting with the blower tube. Rock dust is forced into and through this tube by the revolving worm, this arrangement serving to prevent the establishment of any back pressure from the blower tube into the hopper. Consequently the tube incasing this worm is called the baffle tube.

### PACKING OF DUST PREVENTED

The tendency of a worm arranged as above described is to crowd the dust to one side of the hopper in the direction of translation and to pack it at a point directly over the baffle tube. This is not desirable and to overcome it two other worms are placed above and on either side of the feed worm. These revolve in a direction opposite to that of the main worm, overcoming any tendency of the dust to be crowded in the direction of the feed. Because these two secondary worms are wholly exposed and the feed worm is exposed only on top, they exert a greater action on the dust than the feed worm and keep the dust in constant contact with it.

Lines drawn from center to center of the three worm shafts from a triangle; the axes of the two secondary worms lie in a horizontal plane. The feed worm is driven at 110 r.p.m. by a chain from the shaft of the blower which, in turn, is direct-connected to a motor. The secondary worms are driven at 55 r.p.m. by gears from the shaft of the feed worm. By these means the feed is made positive and there is no arching of dust.

Air is supplied by a 30-in. blower of the company's own design having 3-in. blades. This machine has a normal capacity of about 8,000 cu.ft. at a water gage of 13 in., this being equivalent to the load that a 15-hp. motor (one of the company's standard sizes) will safely carry.

The discharge head or nozzle of this machine is shown in the headpiece. It is of the stationary type,

Fig. 1—The Dust Distributor Car Complete

About 1,500 lb. of limestone dust may be placed in the hopper. This is fed at a uniform rate to the fan blast by means of a worm conveyor while two similar conveyors prevent packing of the dust at one side of the hopper base. About 15-hp. is required to operate this machine.

NOTE—The peculiar looking device shown in the headpiece is the cone-shaped nozzle of the mine dusting machine. It is composed of an inner and an outer shell adjustable with respect to each other. Dust is projected at right angles to the major axis of this nozzle and in greater quantity per linear in. along the curved portion of the periphery than along the straight portion.

Fig. 2—End-on View of Nozzle

As may be seen the dust is blown out at right angles to the longitudinal axis of the nozzle. The dust thus takes the shortest route to the several surfaces of the mine passages to be coated.

cone-shaped except that the bottom is flattened to make its periphery similar in general outline to that of an entry. Inside of the outer shell of the head is another shell of the same general shape but having a more obtuse angle at its vertex. This inner shell can be adjusted inward or outward to decrease or increase the width of the opening surrounding the periphery of the head. The outer end of the inside shell or jet is provided with a flare plate. As the dust enters the head from the blower tube it is confined between the inner and outer shells and consequently is forced outward to the nozzle opening where its direction of travel is again changed by the flare plate.

#### DUST TRAVELS SHORTEST DISTANCE

This diverts the particles of dust to a direction perpendicular to the longitudinal axis of the nozzle; that is, it so directs the dust that its travel, when the machine is working on an entry, is perpendicular to the surface of the roof, ribs and floor respectively. By this means the distance that particles of dust must travel in order to reach the surfaces to be covered, is made the shortest possible and the force of impact is

Fig. 3—Cloud of Dust Blown by Machine

Much experimentation in the evolution of this machine was carried on in the open air. This shows one of the tests being conducted in the yard of the Library shop. The capacity of the machine may be judged from the density of the dust cloud produced.

the greatest. This action is clearly illustrated in Figs. 2 and 3.

The width of the dust discharge opening at the extremity of the nozzle flare is adjustable within limits. A rectangular plate provided with slotted holes to facilitate adjustment is attached by bolts to the lower or straight portion of the periphery, and a curved plate performs the same function for the circular portion. In practice the opening along the circular section of the nozzle is adjusted to  $\frac{3}{4}$  in., while that of the straight section to only  $\frac{3}{8}$  in. The reason for this difference should be apparent. Because some of the dust which is directed to the ribs and roof of an entry falls to the ground, it is not necessary to project as much dust to the floor as to the rest of the perimeter of the entry. The diameter of the circular portion of the nozzle is 30 in. and the length of the chord on the bottom is 28 in.

Flexible joints are employed at both ends of the connecting tube, that is, where the blower tube joins the connecting tube and where this latter joins the head. By this means great flexibility is obtained. Thus the discharge head or nozzle can be raised, lowered, swung to either side or made stationary in any position. It will be noted from an inspection of Fig. 1 that the diameter of the tube connecting the blower with the head or nozzle is gradually increased. The blower tube (not shown in this illustration), also in-

Fig. 4—Special Dust-Train Locomotive

The walk of a horse or mule or the slowest progress of a mine locomotive is too rapid for effective dusting. Consequently this special locomotive was constructed, largely from the odds and ends available at the Library shop, for the express purpose of handling the dust train. It is of small power and low speed, yet it would be advantageous if it could move even more slowly. The next machine of this kind to be constructed will be designed so as to secure this slower movement.

creases in diameter outwardly from the blower toward the discharge head.

For this reason, as the air moves from the blower toward the nozzle, it expands and creates a suction rather than a back pressure in the baffle tube leading from the hopper to the blower tube. When the nozzle is removed and the blower operated at capacity, a vacuum of  $2\frac{1}{4}$  in. is registered in the baffle tube. With the nozzle in place and adjusted to operating position a vacuum of  $\frac{1}{2}$  in. is obtained. It is because of this suction that the hopper need not be entirely closed.

It has been discovered that the speed of a distributor in rock dusting should range from 40 to 100 ft. per min. The ordinary walk of a horse or mule is too rapid and halting for this purpose while the dust discharged in an entry is likely to frighten an animal and at times render him unmanageable. The slowest speed of an ordinary locomotive with all its resistance inserted in the power circuit is too great for the operation of rock dusting. Obviously therefore, some other device must

be employed for this work. The Pittsburgh Coal Co. has developed and begun using what it calls a "mechanical mule." This is nothing more than a low-speed locomotive, one type of which is shown in Fig. 4.

The machine shown was constructed largely from odds and ends found in the Library shop. Briefly, it is chain-driven from a 5-hp. motor, both axles being propelled by this means. Its ordinary speed ranges from 100 to 300 ft. per minute, but this can be reduced to 60 ft. per minute by inserting resistance. It is mechanically controlled by a clutch. The capacity of the motor driving this machine is sufficient for the purpose; if anything, it is slightly too large. The next locomotive of this kind will be built to attain a lower speed than the one shown in Fig. 4.

This mechanical mule is provided with both a trolley and a cable reel. For ordinary work on haulage entries, the trolley, of course, will be used. At the dead ends of butt entries and other similar places where no trolley wire is available the cable will be employed, the reel being capable of carrying about 300 ft. of this conductor, thus enabling the machine to proceed this far beyond the end of the trolley line.

## Making Coke from Non-Coking Coals by Froth Flotation

Non-Coking Coals Resist Coating and Flocculation but Sulphuric Acid Reduces Resistance and Good Coke Can Then Be Made

**M**ANY types of coal either do not coke at all, or do not yield a product strong enough for metallurgical purposes, especially for use in high furnaces. In some cases it has been possible to produce, even from anthracite, a carbonized fuel resembling coke by mixing the material in a pulverized state with pitch and tar, and heating the mixture.

In investigations of a number of non-coking coals, by which is meant coal which does not ordinarily yield coke of the desired strength, it has been found that the surface of the coal particles is such that it resists coating with a binding medium. For example, tar or pitch, or a mixture of these two will not readily adhere to the coal particles and thus promote cohesion.

Wet processes for treating coal, such as the froth flotation concentration process and also various briquetting methods have been fully investigated, and in the course of these studies several non-coking coals have been encountered which, when suspended in water in a pulverized state and subjected to agitation and aeration with a liquid binding medium, do not become coated or flocculated. Such investigations have led to the view that if a non-coking coal can, by any means, be effectively coated and flocculated, a useful coke could be produced.

Three British engineers, Broadbridge, Edser and Beasley, have accordingly devised a process for producing a coke from such coals. This consists in suspending the powdered coal in water and subjecting the mixture to aeration and agitation with a liquefied binding medium, the coal particles becoming flocculated. The product is then briquetted and coked.

Certain coals naturally resist coating and flocculation, but if the surface of the pulverized non-coking coal is treated with a dilute solution of mineral acid, such as sulphuric, and with a liquefied binding agent,

such as tar or a mixture of pitch and tar, the particles will agglomerate and can be coked.

As a rule the acid is added to the circuit liquor itself so as to effect in one operation the treatment with acid and the coating of the particles.

In one process a powdered coal or a froth flotation concentrate is suspended in water and mineral acid of weight equal to 0.1 per cent of the weight of the coal is added. With this is mixed 7 per cent of tar. The mixture is agitated and aerated, and the particles agglomerate. From the agglomerate a good metallurgical coke is obtainable after briquetting to exclude water.

A coal slack obtained from one district in Britain could not be coked at all, and after purification by flotation and direct coking, the best coke obtainable had a strength of only 700 lb. per square inch.

When trying out the new process on this slack 1,200 gm. containing 20.7 per cent ash were crushed to pass a 5-mesh screen and the material was treated by froth flotation, the reagents used being 1 lb. of cresol and  $\frac{3}{4}$  lb. paraffin per ton of slack. The treatment gave 802 g. of concentrate containing 7.5 per cent ash.

The concentrate, plus its own weight of water, was agitated in a froth-flotation cell equipped with an agitator which imparts a vigorous aeration. To it 2.4 lb. of sulphuric acid per ton of concentrate were added and tar to the extent of 7 per cent of the concentrate. The pulp was then heated by steam, and it was noticed that an intense flocculation occurred, the water being easily separable from the froth.

The flocculation was then pressed into briquets at a pressure of 2 tons per square inch, and the product made from it closely resembled a high-grade metallurgical coke, the density being 1.015, and the crushing strength 2,635 lb. per square inch. These results have been confirmed in large-scale tests.

### SAAR VALLEY COAL MAKES COKE

Another coal tested in this manner came from the Saar Valley (France) and consisted of a mixture of bright and dull coal together with carbonaceous shale. The ash content was 24.97 per cent, but was reduced by flotation to 9.12 per cent. This concentrate was screened to separate fines of a size to pass an aperture of 0.008 in. linear, and the fine portion was treated in an acid circuit containing 1 lb. of sulphuric acid per ton.

This fine coal was treated in a cell provided with an agitator, and the binding agent used consisted of 3 parts pitch to 2 parts tar in the proportion of 5 per cent binding medium to the total weight of fine and coarse coal. Steam was admitted and the temperature of the pulp raised to 90 deg. C. After the flocculation of the finer part of the coal, the coarse particles were added during agitation, and the whole material became coated and flocculated. The froth was then drained and briquetted at 2 lb. per square inch.

The briquets were coked in a silica pot which was heated in an electric furnace for two hours at a temperature rising gradually to 1,040 deg. C. The coke produced had a crushing strength of 2,430 lb. per square inch, and the results have subsequently been confirmed on a large scale in a coking oven.

The same concentrate flocculated in the same way but filtered and not briquetted yielded a coke having a crushing strength of 1,038 lb. per square inch. When the coal was neither flocculated nor briquetted the coke produced was not uniform, nor sufficiently homogeneous to justify any tests being made to prove its strength.

## With Air Lift Flood Water Can Be Removed at a Single Inexpensive Setting of Equipment

Difficult Pumping Problems Solved by Use of Compressed Air—  
Three Air Lifts Deliver 2,300 Gal. per Minute—Economy of Installation and Convenience of Operation Distinguishes the Air Lift

BY EDGAR J. GEALY  
Associate Editor, *Coal Age*,  
New York City

LAST MONTH when Herbert Axford, of the Ingersoll-Rand Co., presented his paper at the Scranton Engineers' Club on the operation of an air lift in the mines of the Glen Alden Coal Co., he revived interest in a water-raising system little used at most mines and almost forgotten at others. He showed how in spite of certain disadvantages the air lift can be used in emergencies and also that it can be utilized in cases where the water cannot be removed by a pump, because a pump cannot start the water on its way unless it can be placed near enough to the surface of the water to reduce the suction lift to manageable proportions.

There is nothing mysterious about an air lift. Years ago some of the men who installed them chased all observers away just before the plant at the well was put in operation. Consequently, many people thought some strange contraption or mystic word was necessary to get one in operation. A driller once asked a hydraulic engineer what kind of a fitting he was going to put at the end of the line used in an air lift, and when the engineer said he was going to use a reverse bend the driller thought the engineer was making fun of him. When the engineer finally said that he might not use any kind of fitting whatever, the driller thought he surely was demented.

NOTE—Mine water is used for condensing purposes at the Hampton power plant which is shown in the headpiece, consequently it was imperative to start the unwatering of the flooded areas at once. The reservoir and water hoist shaft are located just beyond the right-hand end of the boiler room.

The air lift operates on the principle that the solid column of water on the outside of the pipe outweighs the column of air and water on the inside and so lifts the water in that column to the surface.

In its use of energy the air lift is relatively inefficient. The ratio of foot-pounds of work done upon the water to the foot-pounds delivered to the electric motor which drives the compressor by which the air pressure is furnished, shows that under good conditions the efficiency of the device is about 40 per cent.

However, at times, the air lift is unusually efficacious when we consider the difficulties attending the use of other methods of raising water. For instance, it has the advantage that all the equipment may be located in any desirable place. Only the air line and discharge pipe need be located in the water. A pump must be set up not much more than 14 ft. above the surface of the water it is to raise; a compressor for an air lift may be located at any height above the water level.

Contrary to common belief the air in an air lift does not blow the water out of the discharge line. If it does in any particular case it indicates a waste of energy.

The outlet of the air line should be a considerable distance below the surface of the water to be raised. Within certain limits, the deeper the better. Considering the vertical distance from the nozzle of the air line to the discharge level of the water as unity, if the air line is 70 per cent submerged, the operating results are satisfactory. When the submergence is only 20 per cent the efficiency of the air lift is extremely low.

One of the most successful recent uses of an air lift was made by the Glen Alden Coal Co. at Scranton. On April 7 the Lackawanna River broke into the Taylor mine of this company. The territory flooded was part of a large drainage area handled by the Hampton pumping station.

#### FIVE BIG PUMPS SUBMERGED

The Hampton pumproom is located in the Clark bed which is above the Dunmore Nos. 1, 2 and 3 bed. In a short time after the river had broken in on the mine the water in the pumproom had risen 14 to 16 ft. above the floor level. The five large 5,000-gal. per minute pumps, each driven by a 1,000-hp. motor, were completely submerged. Only the Oxford and Holden pumps, located in adjacent mines at higher elevations, were left undisturbed. Normally the pumps at these last two mines are used to handle water collected at higher levels than the sump at the Hampton pumproom.

Liberal pumping capacity had been installed at the Hampton pumphouse, usually only one of the five big pumps were required continuously and one of the other pumps used 14 hr. per day. In spite of the large capacity of the station it could not stem the flood, and all the pumps were completely submerged.

#### PUT OLD WATER HOIST IN SERVICE

A 3,500-gal. per minute water hoist located on the surface at the Hampton plant was ordered dismantled a few weeks before the flood. Fortunately, this work had not been started, so after a few hasty repairs it was put in service. This hoist together with the Oxford and Holden pumps were the only important re-

maining pumping units left to handle the flood water.

The Hampton power plant, which is located on the surface near the pumping station, uses mine water for condensing purposes. About 10,500 kva. of generating capacity is in the plant,

and everything depends upon the supply of water from the mines. Consequently the Hampton power plant was in danger of being shut down and it was the water hoist which saved the day.

After the river water had been diverted from the cave hole which had opened into the Taylor mine, the water in the Dunmore Nos. 1, 2 and 3 beds began to lower slightly as it sought its level by flowing into the less accessible basins not previously filled. By April 10 the water in the Hampton pumproom had dropped 10 ft. and on April 12 the first motor was removed for repair. The next day the water was 40 in. above the pumproom floor, but the first pump was started, it being located at a higher level than the other pumps.

On April 30, the first air lift was installed to assist in unwatering the Dunmore beds. On May 2, another air lift was started and later a third was put in operation. The first two air lifts each discharged through 16-in. plain cast-iron pipes. Because much surface water entered the mine and greatly diluted the acidulous mine water, the use of this kind of pipe was successful. The air compressor which supplied the air for all three lifts was located on the surface and was connected to a large receiver which discharged into a 6-in. pipe line.

#### PUMPS RAISED WATER TO SURFACE

The water raised by the lifts was discharged into the Clark bed from which it ran into the Clark bed sump and was raised to the surface by the five centrifugal pumps which had previously been put back into service.

The discharge line was arranged as shown in Fig. 1. A T-connection was installed at the Clark bed level, and a short length of pipe was placed on the upper end of the T to act as a surge chamber. The end of the air line was located about 25 ft. above the Dunmore No. 3 bed, the lowest of the Dunmore seams.

On May 16, the third air lift was installed, but it discharged through a 12-in. pipe. This lift was put into operation because the compressor was sufficiently large to handle this extra load and thus speed up the unwatering process.

In the period extending from April 30 to Aug. 14, 1923, the water pumped by the pumps in the Clark bed was 1,200,000,000 gal. In the same period in 1924 when the air lifts were in operation, 1,860,000,000 gal. of water were discharged at the surface. From this it was estimated—assuming that the inflow during this period was the same both years—that the air lifts raised 660,000,000 gal. while in service. Records show that if the 12-in. line is considered about half the

Fig. 1—Air Lift Unwaters Areas Far Below Pump Level

The air compressor was located on the surface and an air line dropped through the 16-in. discharge pipe. Water in the three Dunmore beds was delivered to the Clark bed pumps. Above the T-connection at the Clark bed were a few lengths of large pipe from which the air separated from the water could escape. Centrifugal pumps raised the water from the Clark bed to the surface. The efficiency of the air lift varied with the submergence from about 40 per cent to 20 per cent.

**Fig. 3—Vertical Pumps Will Operate When Submerged**

The tall building, part of which is shown in the illustration, is a Hudson Coal Co. pumphouse. It contains two large motors which drive two vertical-type centrifugal pumps located in the mines. There is no danger of losing the motors when the pumps are submerged, but the pumps must not be stopped when they are under water. The building is unusually high so that the shaft between a motor and pump can be raised for inspection or repair. Care must be taken that the couplings in the shaft are not loosened for, when the power is shut off, the returning water may drive the impeller as a water wheel and the pump will run backward.

capacity of one of the 16-in. lines the lifts were in service 4,650 air-lift-hours. From this figure it was estimated that the lifts discharged 2,360 gal. per minute. The initial submergence was 77 per cent and the final submergence about 20 per cent. The air pressure was about 45 lb.

Another interesting air-lift installation was made at one of the Hudson Coal Co.'s mines near Jermyn. Here a 24-in. pipe line was used in part of the discharge column and several 36-in. lengths of pipe used at the top.

#### AIR LIFT PROVES EFFICIENT

The Harleigh-Brookwood Coal Co. also recently used an air lift. Here a pump connected to a 14-in. discharge line had been submerged during the rainy season. The column line lay on a steep slope but nevertheless a 3-in. air line was inserted in the discharge pipe and a compressor put to work. Much to the surprise of the engineers the discharge was about 2,200 gal. per minute. The efficiency of the scheme was about 30 per cent. One of the workmen said it was more efficient than the old pump which was submerged.

A story is told of a master mechanic in a New Jersey iron mine combining the air-lift principle with a centrifugal pump. It is said he connected an air pipe into the column line of the pump and started both the pump and compressor. The result was that by this means he could raise the water 50 ft. higher than the pump was capable of doing alone. The conditions under which this was done are not entirely known, but it is understood that the presence of high water made the greater lift necessary. Some engineers are wondering whether such an arrangement is feasible and further investigations are being made.

## Yampa Field May Provide West With Hard Coal

**Anthracitization Varies Much in Any One Area—Ash Content Not Unduly High—Other Coals Are Bituminous And Subbituminous**

The coals of the Yampa field, in Routt and Moffat counties, Colorado, are receiving more attention as progress is being made on the Moffat tunnel. The present steep grade over the Continental Divide of the Denver & Salt Lake R.R., the only line serving this field, is a serious handicap to the transportation of coal to Denver and the Great Plains region.

When the tunnel is completed one ordinary locomotive will haul twenty-two loaded coal cars over the divide in half the time that four Mallet engines now perform the same task. The great value of the tunnel to the coal industry can be made evident by pointing out that the tunnel will save 23 miles of line, 2,406 ft. of lift, and countless delays and blockades by snow and will reduce the gravity load on each coal car by one-half. In anticipation of the impetus to coal development that must follow the completion of the tunnel the coals of this field have recently been sampled by J. Brian Eby of the Geological Survey.

The analyses of the samples of anthracite from the Crawford tract show the variation in the rank of the so-called anthracite coals. In general, anthracite has a fuel ratio that ranges from 10 to 30. One sample, collected 125 ft. from the mouth of the mine, is a good anthracite, whereas another sample collected 95 ft. from the mine mouth is semi-anthracite. Three samples are good anthracite coals of over 12,000 B.t.u., but from the locality at which one was taken the coal rapidly decreases in rank toward the mouth of the mine, 260 ft. distant.

#### LOW-ASH BITUMINOUS COAL

The results of all analyses made of Yampa coals show that the sub-bituminous coals as mined contain an average of 19 per cent moisture, 32 per cent volatile matter, 45 per cent fixed carbon, and 4 per cent ash, and that they have a heating value of about 9,600 B.t.u. The bituminous coals average 9 per cent moisture, 47 per cent fixed carbon, and 5 per cent ash, and have a heating value of 11,600 B.t.u. The anthracite averages 6 per cent moisture, 6 per cent volatile matter, 78 per cent fixed carbon, and 10 per cent ash, and has a heating value of about 12,500 B.t.u.

Samples collected in the same tunnel, however, such as that on the Crawford tract, show that the coal does not hold its anthracitic character over any large area. This condition is due to the fact that the anthracite of this region was formed ages ago by the local alteration of beds of bituminous coal by the heat of adjacent masses of intruded rock. As the beds of anthracite are of uncertain extent, attempts to mine it should be preceded by careful prospecting and sampling, either by tunneling, shafting, or coredrilling. The rank and quantity of the Yampa coals are stated in Bulletins 297 and 748 of the U. S. Geological Survey.

ELECTRIC LAMPS are being introduced at the Rum Creek colliery of the Youngstown Sheet & Tube Co., Dehue, W. Va. This is the first mine in the Logan field to work with closed lights.

# What Changes Should Be Made in Income Tax Laws

Rulings Should Not Be Revised Without Notice and Revision Should Never Be Retroactive—  
All Rulings Should Be Published—Doubtful Items Should Not  
Be Classified as Capital Expense

BY JOHN LAING

President, Kanawha Coal Operators Association,  
Charleston, W. Va.

**P**ERHAPS the taxpayer's most general objection to Federal income-tax legislation is that it leaves him uncertain as to his tax liability. Instances could be multiplied indefinitely of injustices by reason of that uncertainty. Of peculiar importance to the coal-mining industry is the fact that the Solicitor of Internal Revenue in a decision published Sept. 15, 1924, disallowed the deductions made by a coal company to cover coal cars, steel rails, and trolley wire which had been purchased solely because the length of haul had increased. The investment was necessary to maintain the normal output of the mine.

Deductions of this character were specifically allowed by Article 222 of Regulation 45, and by Article 222 of Regulation 62 if my construction of these latter regulations is correct. Many cases have been settled under these rules, and this recent memorandum of the Solicitor represents a complete reversal of the Department's policy, with the result that taxpayers in the future will not receive the same treatment as those in the past and may have many cases reopened which were considered closed.

This is not the only perplexity with regard to tax payments, for in the course of business transactions, parties are often prevented from making sales or entering into contracts for fear of the effect of the income-tax law. In consequence attorneys frequently are obliged to say in such cases that they cannot definitely advise clients as to the effect which such transactions will have upon their income taxes.

The Department refuses to advise parties authoritatively in advance as to what their tax liability will be. In legislation as complicated as the income-tax law, and as far-reaching in its scope, the element of uncertainty cannot be entirely eliminated. Two provisions, however, would greatly lessen this evil. They might be formulated thus:

(a) When the Department has once established a ruling allowing a deduction to the taxpayer, such ruling should not be changed, except so far as it may apply to future years. In other words, where taxpayers, under the rulings of the Department, proceed upon one theory of the law, they should have the advantage of that ruling until they are advised that the Department

has reversed its position, and this reversed position should be applicable only to taxes accruing subsequent thereto.

(b) An agency should be provided whose decision would be binding, to which taxpayers who contemplate entering into business transactions may submit for determination, questions of tax liability, so that the taxpayers may know in advance just how their acts will affect the taxes they will have to pay.

*Unpublished Rulings—*

An element contributing to the uncertainty in the administration of the income-tax law is the practice of the Department of promulgating, for the benefit of tax officials, rulings which are not made public. Attorneys and those practicing before the Department, frequently have the experience of meeting a ruling which has not been given to the public. It would be, of course, impossible and un-

desirable to publish every proceeding in the Department, but any ruling which is to be used as a precedent should be published so that it would be equally available to government officials and to representatives of the taxpayers.

*Expense—*Due to the complicated character of the income-tax law a tremendous expense is placed on the taxpayer. There are two important costs in all complicated income-tax cases—accounting and legal services—entailing upon the taxpayer the double burden of employing an expert accountant to arrive at the facts as disclosed by the books of the taxpayer and a lawyer, or tax expert, to present the legal effect of those facts when ascertained. This two-fold expense is imposed upon the taxpayer in addition to the tax. It would seem that this most burdensome element of the income-tax law is almost inherent and constitutes one of the most serious objections to the law itself.

*Capital Items—*The Department, under the indefinite language of the Act, has shown a disposition to classify all doubtful items as capital expenditures rather than as expenses, thereby depriving the taxpayer of deductions to which he is entitled. I have already noted the recent ruling whereby mine cars and the like, which were purchased by a coal company simply to maintain normal output, were disallowed as a deduction.

In one of the companies in which I and my associates

are interested, the Department has disallowed as a deduction certain surveying expenses to which the company was put to settle its boundary line with an adjoining owner. This surveying was done long after the property was acquired, and the expenditure added nothing whatever to the productive value of the property, but the Department, nevertheless, has classified it as part of the cost of the land. Any item of expenditure which does not add to the productive value of the business should be classified as an expense, and the act should be so amended as to require the allowance of such deductions.

*Delay*—Section 1009 of the Revenue Act of 1924 provides that ordinary internal-revenue taxes shall be assessed within four years after such taxes have become due and no proceeding in court for the collection of such taxes shall be begun after the expiration of five years after the taxes have become due. This provision of itself permits great delay in the settlement of tax matters, and virtually all companies have several years' unadjusted tax liabilities hanging over them.

Though the period during which the government is allowed, under the act, to adjust taxes is unduly long, an even worse situation has developed because the Department frequently virtually requires taxpayers to sign waivers, under the threat, in effect, that if such waivers are not signed, there will be an arbitrary assessment.

As has been said by one writer on income-tax law, this is little better than a "departmental hold-up," and it has prolonged indefinitely, in many instances, the taxpayer's period of uncertainty as to his tax liability. Thus companies, as well as individuals, continually face an unadjusted and unascertained tax liability. This has had a most harmful effect upon the business of the country, particularly in two ways:

(a) Persons are afraid to buy the stock of a corporation for the reason that they will have no means of knowing what the unadjusted tax liability on the company will be.

(b) In many instances, some of which have come within my personal knowledge, the stock of a corporation changed hands through voluntary or involuntary sale. The new owners had no knowledge of the corporation's tax status, and later large additional assessments were made for taxes payable for years prior to the transfer of stock and these, in effect, fell on its new owners.

It would be perhaps impossible entirely to eliminate this condition, but the following are corrective suggestions:

(a) The period in which the government may collect back taxes should be greatly shortened, and, if necessary, additional employees in the Department be authorized, so that they could keep up with the work. I believe, however, that if the present facilities and help of the Department were applied with anything like the efficiency of a private enterprise, such additional employees would not be necessary.

(b) The Department should not be allowed to request

waivers from the taxpayers and should not be permitted to make a reassessment upon an arbitrary basis nor until after a thorough examination has been made.

In dealing with this matter I am treating more of the abuses under the old acts and these abuses may in part have been cured by the act of 1924, but I much doubt if this is so. Much depends upon the way in which the Department administers the new act.

*Publicity of Return*—Section 257 of the Revenue Act of 1924 provides that returns upon which the tax has been determined shall constitute public records and shall be open for inspection only upon order of the President and for the benefit of certain committees of the Senate or the House, certain officers of any state and a certain percentage of shareholders. This provision has been

much discussed and its injustice is apparent. It holds out the possibility, at least, of any business being made the subject of partisan and political scrutiny. The section further provides that a list containing the names of taxpayers, together with the income tax paid by them shall be made available to public inspection. Under this provision any competitor can ascertain year by year the income tax that is being paid by his rival, and through that knowledge he can easily de-

termine his competitor's net income. Many other abuses could be cited which would undoubtedly arise under this provision, not the least of which is that knowledge of every one's net income will be in the possession of anyone who has sufficient curiosity to look at the list and estimate the income from the tax paid.

This provision, which was inserted in the act of 1924 under the stress of political agitation, is, in my opinion, wholly bad and should be eliminated from the act. Its effect on the coal-mining industry would be particularly unfortunate in case of labor troubles or the attacks of demagogues. Knowledge of the income tax paid by various companies in a preceding year, with the resultant knowledge of what the net income was, would be a potent weapon in the hands of the enemies of the industry.

*Net Loss*—Section 206 of the act of 1924 provides that a net loss in the conduct of a business may be applied against income for the next two succeeding years. This step is an improvement over previous income-tax legislation. However, where the industry has a prolonged depression and where a company is in a formative period, two years is too short a period and should be extended.

*Formality of adjustments*—Section 1005 of the act of 1924 provides that there shall be only one inspection of the taxpayer's books, unless the taxpayer requests otherwise, or unless the commissioner, after investigation, notifies the taxpayer in writing that an additional inspection is necessary. In practice, even under the similar provision of the 1921 act, the Department has subjected the taxpayer to more than one examination. I have personal knowledge of this in some of the companies in which I am interested. This section should be amended so as to permit only one examination, unless

---

**W**HEN MINES are extended, mine cars, trolley wires and steel rails have to be purchased to maintain tonnage. Hitherto these have been listed as current expenses under the departmental rulings, yet a decision has been rendered recently classing these expenditures as additions to capital. This not only affects future tax payments, but puts in question past settlements adding to the grave uncertainties in which the whole question of taxes is at present involved. Mr. Laing in this article indicates what changes in the laws would assist in remedying fundamental injustices in the levying of income taxes.

---

the taxpayer requests otherwise, or unless there is reason to believe that the first examination has been rendered inadequate by reason of fraud or concealment on the part of the taxpayer.

The mere notice of the commissioner should not be sufficient to make an additional investigation permissible. This provision is virtually equivalent to permitting the Department itself to determine when it will do its work over again. Section 1006 provides that after a determination and assessment in any case, or acceptance of any abatement, credit or refund, "an agreement may be made in writing between the taxpayer and the commissioner, with the approval of the Secretary, that such determination shall be final." In practice it is comparatively difficult for the taxpayer to obtain the benefit of this section.

When such an agreement is requested the Department usually makes a re-examination of the taxpayer's books, even though they have been considered closed. Attorneys have the impression that the taxpayer runs a risk in asking for such an agreement. On the other hand, it is of the greatest importance to a taxpayer that he be assured within a reasonable time that his tax matters for any one year are closed and cannot be opened. This is particularly important where he is contemplating a

sale of his property and desires to assure the purchaser with respect to tax liability.

A provision should be added to the law that whenever the government sends out a 60-day notice (as provided in section 274 of the Act) advising taxpayers of a deficiency in tax, it be precluded from claiming any greater tax and that upon an adjustment between the unit and the taxpayer after such a notice, whether there is an appeal to the board or not, the tax matters for that year be automatically closed with no power in the Department to reopen them, except upon a showing of actual fraud or concealment upon the part of the taxpayer.

In other words, whenever there has been an adjustment for any one year between the taxpayer and the government, it should be considered final in the absence of fraud, even though no formal agreement has been signed. No injustice could be done the government, for the reason that it need make no financial adjustment until it has inspected the taxpayer's books. On the other hand, such provision, coupled with shortening the time in which the government shall have to collect taxes, would greatly shorten the period of uncertainty as to taxes for past years, which is now so great a burden to taxpayers.

## High-Pressure Rock Dusting In Utah Coal Mines

Use Water Lines, Pack Mules and Sledges to Convey  
Dust—Barriers Made Useless by  
Absorption of Moisture

AT CASTLE GATE No. 2 mine the height of the roadways makes high-pressure dusting essential and a larger quantity of dust has to be used, than in a mine the roadways of which have a lesser perimeter. For this reason a 10x10-in. portable compressor giving a nozzle pressure of 70 lb. per square inch is used and about 3.5 lb. of rock dust is distributed per lineal foot. The limestone dust used is obtained from a cement company which pulverizes the material to a fineness suited to the manufacture of cement.

For reaching parts of the mine not equipped with electrical current, as well as to economize in the moving of the machine, the water lines are drained and blown out to free them of water and are then connected to the dusting machine. By this means dust has been delivered under sufficient pressure a distance of 3,600 ft. down a 12-per cent pitch, using the 3-in. water line already in place. Roadways also have been dusted successfully 7,200 ft. from the compressor using a 4-in. water line which lay up the slope from the compressor on a 6 per cent average grade. It is purposed to station a 12x12-in. compressor in the power house at Castle Gate No. 1 for this purpose. About the Sunnyside dusting plant, where the same pressure system has been used with a 10x10-in. portable compressor, the following information is available: The air pipe leading from the compressor to the injection nozzle is 1 in. and the pipe from the injector to the dust line is 1½ in., the nozzle itself being ½ in. The pressure at the compressor is 80 lb., and the safety valve opens at 90 lb. At the injector nozzle the pressure is 70 lb. A 12-ft. length of 1½-in. pipe is used on the dust line. Where 20 ft. of pipe was employed the friction was excessive. Figuring 75 lb. of dust per sack, the machine throws dust

at the rate of 15 lb. per minute. From 35 to 50 sacks of dust are used every eight hours depending on conditions. This will cover 700 to 1,500 ft. of entry with an average of 838 ft. per shift.

### WATER PIPES CONVEY DUST

At this mine also water pipes have been used successfully for dust distribution. On an average, 3.4 lb. of dust is used per lineal foot of entry, this figure includes the dust used in the crosscuts which are dusted as far back as the stoppings. Where difficulty was experienced in reaching points in untracked airways dust was conveyed on pack mules and sleds.

### Cost of Dusting at Sunnyside, Utah

Application	
Labor .....	\$0.035 per lineal ft.
Material .....	0.017 per lineal ft.
Repairs	
Labor .....	0.007 per lineal ft.
Material .....	0.008 per lineal ft.
Total .....	\$0.067 per lineal ft.

In the use of dust for the barriers in return airways the Utah Fuel Co. has found, says A. C. Watts, the chief engineer and geologist, that the unprotected dust will become so moist in three days' time that it can be balled up in the hand and that no dust cloud is raised when dust barriers are tripped. Even when the dust is covered with brattice cloth the result is the same.

Waxed paper, such as comes in powder boxes, was used for holding the dust. It prevented absorption of moisture for about 10 days. Dust was then placed in a cardboard detonator box with a tight lid. In two weeks the box was soggy with moisture and the dust on top would not form a dust cloud, but the dust in the center of the box was dry. With dust costing \$6.50 to \$7 per ton, the use of barriers in moist back entries becomes prohibitive.

NEVER HAVING entered a coal barony himself, John L. Lewis is without sin and therefore yearns to cast out the first Stone.

## News Of the Industry

### Need of Accurate Coal Output Figures Again Emphasized

Industry Frequently Forced to Do Business in Dark—Shortage in 1920  
Greatly Exaggerated Because of Lack of Dependable Data—  
“Phony” Statistics Worse Than None

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

The generally held opinion that it is imperative to have more coal statistics frequently has been reflected in this correspondence. Arguments for these statistics, when boiled down, are based on the inadvisability of attempting to do business in the dark. The classic illustration of the need for more good statistics is reference to 1920, when a real shortage of coal was exaggerated greatly in the public mind. Had it been known at that time after the critical period, which was ended in June, that stocks were increasing steadily, the frenzied buyers might have realized that the emergency had passed. As it was they did not know that stocks were increasing and the disturbance of the market continued for months. In fact it reached its peak in October, when stocks had climbed to the level of comfort.

The current issue of the *Purchasor*, the semi-monthly publication of the National Association of Purchasing Agents, furnishes an illustration of a different kind of danger—the danger of inaccurate statistics. Perhaps a better word would be “phony” statistics. Since late in 1922 the association periodical has carried a current survey of stocks and consumption of coal. The basis of the charts which are printed is not revealed. They are said to be constructed from returns from members of the association—a membership which represents a buying power of many million tons of coal annually.

#### Important Essential Missing

An examination of the charts indicates that the consumption which they purport to show sometimes runs as high as 48,000,000 tons a month, or in other words, practically the total consumption of coal. An essential of the statistics—the number of firms reporting—is omitted. On this point the association never has enlightened the public.

The possible harm that such ex-parte statistics can do is illustrated by the latest report which covers the month of October. It states that from Oct. 1 to Nov. 1 the stocks of industrial users increased 25,000,000 tons. The *Pur-*

*chasor* is so sure of its data that it can tell you the exact number of tons in stock. The more cautious Geological Survey and Census Bureau, in their statements based on written replies from more than 5,000 consumers, never dare to claim an accuracy closer than two or three million tons, but the *Purchasor* has it figured down to the last ton. On Oct. 1 stocks are declared to be 52,468,725 net tons and on Nov. 1 they are shown to be 77,754,068 net tons. In other words, in the brief space of thirty-one days there went into storage exactly 25,285,343 tons.

#### Discrepancy Evident

The coal trade was not aware of its extraordinary performance in October. The *Purchasor* tells the producers that they have mined coal enough in one month to put 25,000,000 tons into storage, besides meeting the current consumption. It is true that when the coal man looks at the *Purchasor's* chart he is bound to be puzzled in figuring out how this could be because the total tonnage produced, according to the *Purchasor*, was only 55,000,000 tons, while the industries themselves (not including “coal consumed for industrial heating and consumed by the householder”) used about 35,000,000 tons. Such a discrepancy seems not to worry the *Purchasor*. An advance proof of the statistical article was sent to the National Coal Association. It was hurried back with the discrepancies noted. This communication was acknowledged with the statement that corrected proofs were being forwarded. The corrected proofs were not received and the *Purchasor* was printed with the original material unchanged.

There is no inclination to question the good faith of the purchasing agents or their fuel committee. It must be admitted that they have had reason to complain against the service they have been given by the coal industry on occasions. But there is no getting around the fact that the circulation of much claims of sudden enormous additions to stocks have a most injurious effect on the coal operator. Prices already are below a living level.

There was an addition to stocks in

### What Illinois Miners Earn

Those Illinois miners who worked during October averaged a weekly pay of \$36.17 and in November, \$29.78, according to the monthly report of the state Department of Labor. The same number of names appeared on the various mining company payrolls during both months. The average earnings of the miners thus dropped 10.6 per cent. The reported running time of the state dropped only 2 per cent from 49.4 per cent of full running time in October to 47.4 per cent in November. Therefore it could be deduced that Illinois miners fortunate enough to have work are still able to buy gasoline for their motor cars. But the fact that several mines with big payrolls have worked almost continuously during those two months indicates that a considerable share of the total wages of the state have gone to a comparatively few men. The rest are in the same condition as the union miners in most other parts of the land.

October. A brief study of the official data on production in the last stock report of the Geological Survey and the Bureau of the Census shows that the addition could not have been 25,000,000 tons. It is entirely obvious that stocks were augmented by much less than 5,000,000 tons. The claim to 25,000,000 tons is preposterous. It would mean an addition to stocks such as never have taken place before, even in periods of frenzied buying before a strike.

The feeling at the National Coal Association is that the producers have a right to protest against any such rigging of the coal market to the advantage of the buyer. Producers and consumers of coal alike are agreed that the trade needs figures on stocks more than any others, but it is regarded as obvious that these figures should be compiled and published by a neutral agency that could have no interest in doctoring the results.

In the Dec. 4 issue of *Coal Age* the National Association of Purchasing Agents stated that the amount of hard and soft coal in storage in the bins of users in the United States and Canada as of Nov. 1 was 77,754,068 net tons, an increase of 25,285,343 tons over Oct. 1. These figures should be corrected to read 57,754,068 tons and 5,285,343 tons respectively.

## Spread of Central Heating Foreseen in Canada

Central and district heating, having shown economies, probably will be adopted to an increasing extent in Canada, according to a report by the Dominion Fuel Board following a recent investigation. In addition to the saving effected by the substitution of low-grade fuels and refuse, other advantages are the elimination of smoke, dust and dirt, reduced fire risk, ease of regulation, uniformity of temperature, relief of street traffic from coal and ash haulage and appreciation in value of property.

One of the essentials to success in district heating, the report points out, is density of load, and for this reason it cannot be successfully adopted in towns of less than 4,000 population, and if other conditions are not favorable, the minimum population for economic operation is 10,000.

The cost of service can be lessened sometimes by combining the heating plant with a steam electric generating or an industrial plant. Even in the most efficient steam engines and steam turbine generators only 15 per cent of heat in the steam is utilized for heating. At the district heating plant at North Battleford, Saskatchewan, for instance, exhaust steam from the municipally-owned steam electric generating system is used for heating.

The benefits to be derived by consumers, the report states, are not so much in cost as in increased convenience, cleanliness and relief from handling ashes. A great deal depends, it is pointed out, on the cost of fuel available, but under ordinary conditions it has been generally established that to give the heating company a reasonable return a rate must be charged for dwellings in excess of the cost of fuel for individual heating.

Among the interesting facts brought out by the inquiry is the fact that despite its hydro-electric power development the province of Ontario consumes 60 per cent of the coal requirements of the whole Dominion. Another curious fact is that in spite of the difference in temperature coal consumption for heating buildings in Canada is slightly less than in the northern United States. In

## Coal Review Discontinued

*Coal Review*, published weekly for several years by the National Coal Association, will be discontinued after the issue of Dec. 24, 1924, and in its stead Saturday bulletins direct to the membership of the association will be resumed and news releases for Tuesdays, covering statistical, traffic and other information of the association, will be prepared for coal trade and other papers, according to announcement by Harry L. Gandy, executive secretary of the association. A monthly résumé of news will be furnished to monthly trade papers.

"*Coal Review* was established in March, 1920," says Mr. Gandy, "when there was urgent need for the publication of such a magazine by the National Coal Association. Conditions have changed, however, and, that need having passed, the executive committee decided the field would be thoroughly served by the other coal trade publications. This change of association policy, it is believed, will result in a more intimate contact between the Washington office and the membership, and in an increasingly helpful and friendly relationship between the association and the various trade and other papers.

"C. B. Huntress, associate editor of *Coal Review*, will be director of information service for the association and will be available to trade and other publications not only in respect to the weekly news release but for special articles and the covering of special events. The program of the association contemplates a wide range of information service concerning the bituminous coal industry."

fact in the heating of dwellings it is appreciably less. This, it is stated, is due to better building construction and the use of double windows in Canada; to the greater use of hot water radiation and to the fact that Canadians are used to lower indoor temperatures than are people of the northern states.

## British Coal Industry Prosperous in 1923, Due Mainly to Ruhr Upset

Owing mainly to the dislocation of production from the Ruhr coal field, 1923 was a prosperous year for the British coal mining industry, states the third annual report of the British Secretary of Mines, recently issued. Output was higher than in any previous year, except 1913; exports surpassed even that "record" year; prices were good and earnings improved on the low level of the preceding year. Output in 1923 totaled 276,000,000 tons, compared with 249,666,666 tons in 1922 and 287,500,000 tons in 1913.

Employment during 1923 was good. At the beginning of the year only 4.5 per cent of the insured coal miners were unemployed, and at the end the number had fallen to 2.4 per cent. This decline was reflected in the increased number of wage earners on colliery books. At the end of 1922 they numbered 1,129,539, and a year later they totaled 1,184,786. Coal was wound at the pits on 277 days on the average, or 15 more than in 1922.

### Home Consumption Drops

The prosperity of the export trade last year was chiefly attributable to the occupation of the Ruhr. Seventy-eight million tons of coal (excluding 1,485,000 tons shipped to Irish Free State ports during April to December) and 4,000,000 tons of coke were exported during the year, as compared with 73,500,000 tons of coal and 1,250,000 tons of coke exported in 1913, which was the highest level previously recorded. The British home consumption of coal was less by 15,000,000 tons than in 1913, although the quantity available was 11,000,000 tons more than in 1922.

In a long comparison of the results of the operation of the national wage agreement between the years 1922 and 1923 the report shows that though there was an improvement last year in both the gross proceeds per ton and in "costs other than wages," the average increase in the actual wages paid was only about 2d. per ton, or 1d. per shift.

## West Virginia Coal Mining Institute

With its spirits unruffled by the heavy technical diet which the program committee had provided. However, it must be remembered that this was taken at "recess" when spirits bowed down by rock dust, pneumatic separation and electrification of gaseous mines were let loose to contemplate less serious matters.

## Coal Output in Canada Up In September, but Still Behind 5-Year Average

Output of coal from Canada mines during September, 1924, according to a report by the Dominion Bureau of Statistics, amounted to 902,595 net tons, an increase of 28 per cent over the tonnage for the previous month, but 35 per cent below the average for the month for the past five years. The greatest increase was 132,000 tons in Alberta to a total of 265,000 tons for the month. The remaining provinces in order of their gains in output were Nova Scotia, up 66,000 tons to a total of 471,000 tons; New Brunswick, 6,000 tons increase to 18,000 tons in all, and Saskatchewan, 1,000 tons more with 17,000 tons output. British Columbia's output declined from 137,000 tons to 132,000 tons.

Comparison of September and August figures covering the total importation of coal from the United States and Great Britain shows an increase of 1 per cent. September imports amounted to 1,587,613 tons while in August 1,557,141 tons was brought in. The September importations this year were 11 per cent lower than the five-year average for the month. During the month 13,620 tons was imported from Great Britain. Total importation of coal for the nine months of 1924 was 12,165,436 tons, or only 7 per cent below the preceding five-year average for the period.

The imports of anthracite for September totaled 327,949 tons. This was slightly less than in August, and about 1 per cent less than the five-year average for the month. Anthracite imported from the United States amounted to 314,329 tons, while 13,620 tons came from Great Britain. The total amount of anthracite imported during the nine months of 1924 was 2,969,224 tons, a decrease of 8 per cent from the five-year average for this period.

The exports of Canadian coal for September were 13 per cent lower than in August. The quantities were: September, 55,353 tons, and August, 63,415 tons. Comparison of the September exports with the preceding five-year average showed a decrease of about 67 per cent. Exports from the eastern provinces amounted to 35,297 tons, an

## New Stunt in Canada

The formation by a vote of 290 to 10 on Dec. 7 of a British Columbia miners' association by Crows Nest Pass Coal Co. men who quit the union represents an interesting experiment. The agreement between the men and the company, reported in *Coal Age* last week, calls for a wage 55 per cent above 1914 scale and slightly above that now paid on Vancouver Island. This means about \$5.20 per day. Contract men are expected to earn about \$8 a day. The new contract runs four years but the company agrees to increase wages if business justifies it. The company's mines have all been shut down because of lack of trade.

increase of 636 tons above August; those from the western provinces amounted to 20,056 tons, a decrease of 8,698 tons below August. The cumulative exports for the year to date amounted to 537,551 tons or 64 per cent less than the five-year average.

Computed from figures on output, imports and exports, the quantity of coal made available for consumption increased about 18 per cent above the figures for the previous month. During September the total was 2,434,855 tons as against 2,196,346 tons for August. In comparison with the five-year average for the month, the September available tonnage was lower by 19 per cent. The total coal made available for use in the first nine months of 1924 amounted to 20,777,022 tons and for the twelve months ending Sept. 30 the total coal made available for consumption was 29,910,548 tons.

The total number of men employed in the coal mines of Canada during September was 21,639, of whom 16,492 worked underground and 5,147 on surface, as compared with a total of 19,280 in August, of whom 14,682 worked underground and 4,598 on surface. The monthly production per man was 41.7 tons for September as against 35.4 tons per man for August. During September the production per man-day was 2.3 tons, as compared with 1.9 tons in August. The tonnage lost was due largely to lack of orders in September.

## This Union State Increased Its Coal Output

Arkansas produced 204,240 tons more of coal during the fiscal year ending last June 30 than it yielded the previous year, according to the report of Jesse Redyard, state mine inspector. The 192 mines of the state, of which only 80 were active, raised a total output of 1,298,791 tons. Of the inactive mines 63 were idle and 49 abandoned. Of the total, 101 are slopes, 44 are shafts, 16 are strip pits and 1 is a drift mine. The underground mines are ventilated thus: 78 by exhaust fans, 31 by furnaces and 53 by natural ventilation. Men employed totaled 3,597, 95 of whom were hurt during the year. The production per fatality was 593,896 tons and per non-fatal accident, 12,503 tons.

## Seek Greater Safety in Hard Coal Mines

Mine inspectors, representatives of the coal companies and representatives of the mine workers of the anthracite field will meet in Wilkes-Barre, Pa., on Feb. 24, 1925, for the purpose of discussing various methods of preventing and reducing fatalities and accidents in the hard coal mines. Officials of districts 1, 7 and 9 of the United Mine Workers will be invited to the meeting. A detailed program relating to subjects of importance to all engaged in the mining industry is being arranged. Among the papers to be read are "Falls of Roof," "Accidents from Mine Cars," "Premature Blasts," "Exploding Gas" and "Mine Fires." Several speakers of national repute will address the meeting. The meeting is being arranged under the auspices of the National Safety Associations. S. D. War-riner will secure the representatives of the operators.

## Confirm Meyer and Campbell

The Senate on Dec. 10 confirmed the nominations of Commissioners B. H. Meyer and J. B. Campbell, whose names had been sent by President Coolidge for reappointment as members of the Interstate Commerce Commission. Their present terms expire Dec. 31.

## Bain's Annual Report Outlines Year's Work Of Bureau of Mines

Accidents in the coal mines of the United States, with their consequent train of deaths, injuries, and tremendous property losses, continue to be too frequent despite the results of modern research which have demonstrated clearly the principal causes and definite means of minimization of such accidents, Director H. Foster Bain of the Bureau of Mines points out in his annual report to the Secretary of the Interior.

For the 13 years 1911 to 1923, inclusive, the Bureau's records show 23,822 lives lost through all classes of accidents at bituminous mines in the United States. Explosions of gas and coal dust caused 3,185 deaths, or 13 per cent of the total. Most of the larger explosions were propagated through the mine workings by coal dust chiefly and therefore coal dust was responsible for the greater part of the loss of life. This extension of an explosion throughout a mine can be stopped even if all initial explosions are not prevented.

Despite the general good will of miners, mine operators, state inspectors and manufacturers of explosives and machinery the tested recommendations of the Bureau have not been adopted in the mines as rapidly or as broadly as is necessary if the loss of lives is to be stopped, the report declares. Consequently, although there has been real progress, as in the decreased loss of life due to accidents from explosives, the death rate from gas and dust explosions is now as great as ever. One state, Utah, following a mine disaster that caused the loss of 171 lives, has adopted every practical tested method of preventing or limiting gas and dust explosions, and is having these methods introduced in the mines as rapidly as possible. An active campaign of field demonstrations is necessary to bring home to those in other states the danger that has become so familiar as to be frequently overlooked and to show that effective precautionary methods are known and available.

The dominant features of the Bureau's efforts during the year to increase safety in mining have been the development of international co-operation with the Mines Department of Great Britain for research looking to the reduction of mine accidents; an intensive campaign for the adoption of rock dusting as a preventive of disastrous explosions in bituminous coal mines and an extensive study relative to the safe use of electricity in coal mines.

The Bureau of Mines considers that had the coal mines of the country in past years followed the principle of rock dusting the mines as a means of preventing the spread of explosions many large mine disasters would not have occurred and hundreds of lives could have been saved. In view of the large number of deaths from explosions during and since 1922 the Bureau urges that the practice of rock dusting be adopted as soon as practicable in all bituminous mines in which dust constitutes a hazard.

Ever since its establishment the Bureau has strongly urged the use of

## Bed of Dried Up Waterway Proves Coal Mine

Although the prolonged period of dry weather has helped the coal business in some localities it has proved the opposite in certain sections of New Jersey near the abandoned Morris Canal.

Persons living along it at Hackensack and Port Murray made the discovery recently that the dry bed of the waterway contains tons of coal which dropped from passing barges in the years that mules towed craft down the canal. At some places boats must have overturned, for mounds of coal have been found.

News of the discovery spread rapidly, for scores of persons, some from as far away as ten miles, quickly began gathering up coal.

"permissible" explosives in all coal mines where there is any hazard from gas and dust, and the amount of "permissibles" used has steadily increased. However, while this increase has been steady, the replacement of other explosives by "permissibles" has not been as rapid as it should be, in view of the known effectiveness and greater security of "permissibles."

During the fiscal year the Bureau studied the possibilities of radio as a means of establishing communication between miners trapped underground following mine fires and explosions and rescue parties on the surface. The results give some promise of the possible development of a satisfactory system of communication through what is known as line-radio, which utilizes metal piping, wiring, car tracks and other permanent metal equipment as carriers for the voice.

A lignite carbonizer recently designed by the Bureau after extensive investigations should, it is believed, result in the ultimate solution of the tremendously important problem of economic utilization of the lignites of the Northwest. These lignites comprise nearly one-third of the total solid fuel resources of the United States.

## State Mine Inspector Wants Colorado Made Safer

A new coal mining safety code for Colorado is embodied in a bill which James Dalrymple, state mine inspector, has prepared for the next session of the Legislature. It follows along the lines laid down in the strict Utah state mining code adopted in that state after the Castlegate mine blast. Mr. Dalrymple would insist upon rock dusting and adequate sprinkling and would make a number of other safety practices compulsory. Incidentally he wants his own office and staff placed under civil-service regulations.

The suggested legislation would require that superintendents be held equally responsible with mine foreman for safe conditions underground; that all mine officials pass periodic examinations for competence; that coal-cutting and coal-loading machines be equipped with water lines to reduce dust; that open-flame lamps be barred; that every man entering a mine shall be searched for "intoxicating liquors, matches, pipes, cigars, cigarettes or any device for making lights or fire not authorized or approved"; that all shotfirers be certified, that they must always test for gas and never fire a shot in an atmosphere where gas can be detected by a safety lamp; that no explosives be used except permissibles and the quantity per shot be limited and that all shot-holes be tamped to the mouth with clay or other incombustible.

## Dusting or Sprinkling Required

Rock dusting would be required from mine openings to room necks, on all haulageways, aircourses and active entries, with dust barriers at strategic places. The law would give the inspector power to shut down any mine which did not keep its dust in the mine up to the required safety proportion. But it would be permissible for mines which did not rock dust to maintain safety by sprinkling liberally throughout a mine so that its coal dust should at all times contain at least 30 per cent water by volume.

Special Man Trip at Gary No. 6 Mines

This trip with cars covered with white duck for the occasion took the members of the West Virginia Coal Mining Institute into the mines to see the O'Toole cutting and loading machine.

## Equal Opportunity for All in Business Is Aim of O. D. Young, Says Hoover

More than 1,000 leading men in all fields of endeavor accorded a remarkable tribute to Owen D. Young, co-author and first administrator of the Dawes plan, at a dinner in the Waldorf-Astoria, New York City, Dec. 11. Among those who lauded Mr. Young for his part in the economic reconstruction of Europe was Herbert Hoover, Secretary of Commerce, who spoke as follows:

"The German reparations had become one of the world's most dangerous inheritances from the war. The sequent failures in its adjustment had poured an increasing stream of conflict into international life, carrying with it political jeopardy and economic demoralization with its train of millions of unemployed and suffering.

"The accomplishment of its settlement involved great economic questions of production and distribution, of currency, of credit, of taxes, and of exchange. Solution has been found in denominations of money and goods, in the creation of complex agencies of finance and government. But there springs from the settlement something far greater than the denomination of these quantities and the working of this machinery of government. It has turned millions of men from discouragement to hope. It has revived the forces of courage and enterprise. It has done even more. It has defeated the forces of hate, and advanced the tide of peace in the hearts of men.

### Adjustment Is Far Reaching

"While this adjustment primarily advances the welfare of the nations of Europe, it reaches far afield in the world. Unemployment and suppressed production anywhere in the world are in the long view a world loss. This restoration of confidence and hope and enterprise, this restoration of commerce, of productivity, and of employment, this relief of suffering in a great nation, is a world asset. As a people we also participate in its blessings. Some part of our growing demand for labor, some part of the increased prices already realized by our sorely distressed agriculture, have come from this restoration of economic vigor and hope in Europe. It is a great thing to have contributed so much to this achievement.

"The wounds to our complex and intricate civilization from the war were so deep and so vital that many had despaired lest statesmanship would be unequal to their healing. Six years since the armistice seems a long time to those who live it and partake of its anxieties. Six years is a trifle in human history, and yet within it, one by one, these great problems of reconstruction have been solved. Surely in this new accomplishment for which we justly give tribute tonight we see again renewed confidence, hope and faith in human institutions. There are indeed many problems yet unsolved, but none of those before us are as dangerous to the restoration of civilization as those

that have already been successfully met in these six years.

"Some have doubted whether the enormous liabilities established under this settlement can be discharged. There are those who have contended that no great external contributions from one nation to another can be economically sustained. Without debating this question I may be permitted to offer one thought in this connection. The payments provided in such settlements must find their substance from production and economic services rendered. These international obligations are huge burdens, but in the course of years any burden shrinks in weight in proportion as the productivity of a nation grows. When the world keeps peace it doubles its international trade once in nearly every score of years.

"The processes of industry and commerce are the cells which heal the injuries of the economic world. They cannot multiply in the noxious air of conflict and political uncertainty. The settlement to which our guest has contributed so much clears the atmosphere, and the magical multiplication of these cells will quickly provide the strength to meet the burdens—if the world keeps the peace.

"But beyond even these special occasions of vivid public service, Mr. Young has made a still further contribution to American life—perhaps the greatest of all his contributions. That is in his display of the fine sense of the responsibility which today rests upon those who administer our largest industries.

### Would Preserve Initiative

"Manufacture and distribution on a vast scale is the foundation of our high standard of living and the general comfort of our people. It can be accomplished in no other way than through the development of great units of production. With their development have come innumerable problems of public relationship and public responsibility. We are in fact today witnessing a rapid evolution and perhaps a silent revolution in the relationship of great business to our social system. We are struggling to preserve the fundamental stimulus of action, of initiative and competition, to hold open the avenues of opportunity. At the same time we are struggling to gain the benefits of co-operative action.

"In this period of evolution nothing is more needed than clear vision of their public responsibilities on the part of our industrial leaders. For here is a triple trusteeship—a trusteeship to the owners who ultimately must be comprised from the savings of those who endeavor to provide security for their dependents and for their old age. These must have proper stimulative return as a reward for their enterprise and their self-denial. There is the trusteeship for a vast body of employees that they should have stability in employment and a sense of security for work conscientiously performed, that they should have a growing standard of living and comfort, and full

### Postponed Again

Secretary McGinty of the Interstate Commerce Commission announced last week that the commission has decided to postpone further the effective date in the so-called assigned coal car case—Docket 12530. The order, which was to have become effective Dec. 15, has now been deferred until Jan. 15, 1925.

opportunities for recreation and education.

"There is an equal trusteeship to the whole public who are served by the products of these enterprises. It is in the public interest that the product should be multiplied; should be given with every advantage of technical excellence and service and upon the best terms which can be attained with due regard to the two other strong obligations toward which our leaders must also look. This trusteeship goes even further. Constant gains to each group depend upon the elimination of waste and the constant development of science and invention, of increasingly more efficient organization. Beyond this again these organizations must be held high in the business and ethical relations by the character of their leaders. They must be conducted in a fine sense of non-interference with human rights.

"I know of no responsibility larger than that imposed upon the headship of great industries, for from their leadership and their vision must come not only great contributions to our economic progress but upon it depend the solution of the many social problems which confront us. We have a real and growing measure of this sense throughout American industry. And Mr. Young has been the expression of this type of leadership.

"There is one final thought to which I should like to give expression. Our friend and his colleagues in entering upon this mission to Europe, and in contributing so much to its high accomplishment, occupied the unique position of private citizens. Mr. Young is honored tonight as a private citizen. Does this not illuminate the potency and possibilities of private citizenship in a real democracy? Here is a world service of sublime accomplishment rendered by individuals bearing none of the trappings of public office but who nevertheless were accepted as the representatives of the intelligence and instinct, good will and faith of the American people—and represented it to the pride of their countrymen."

### New Haven R.R. Opens Bids

Bids opened Dec. 15 by the New York, New Haven & Hartford R.R. for 360,000 to 410,000 gross tons of high-volatile run of mine bituminous coal, to be delivered in substantially equal monthly quantities between May 1, 1925, and May 1, 1926, disclosed twenty-one tenders from twelve bidders. The quotations ranged from \$4.80 to \$5.50 per gross ton alongside, Boston. This is the second set of bids submitted, the first batch, opened Nov. 17, having been rejected.

## Practical Pointers For Electrical And Mechanical Men

### By Large Mandrels Old Locomotive Motor Frames Are Made Like New

**Pittsburgh Coal Co. Brings All Worn Equipment up to Standard—  
Uses Mandrels to Fit All Types of Motors—Large  
Stock of Repaired Parts on Hand**

EVERY MINE electrician or mechanic concerned with the upkeep of old equipment knows the difficulties which arise when the motor cases of mine locomotive motors become worn so that the bearing housings and axle brasses do not fit properly. Such difficulties as arise can be overcome by the use of over-sized parts, however this is highly unsatisfactory because most of these over-sized parts are more expensive and their use complicates the economical and expedient handling of repair work.

Even though a mining company has a lathe or boring mill large enough to accommodate a motor field frame it is difficult and time-consuming to set up the frame properly so that the machining will be true. The Pittsburgh Coal Co. makes a practice of building all worn equipment up to standard and also has solved many of the difficulties of chucking. Mandrels to fit the various types of motors have been provided.

#### FIVE MANDRELS USED

Fig. 3 shows one of the five mandrels used at the company's central shop at Library, Pa. By the use of shoes or liners one mandrel may be adapted to several sizes. The stock of five mandrels and several sets of shoes takes

**Fig. 2—Motor Frame Set Up in the Lathe Ready for Work**

The use of the mandrel on which a locomotive motor frame is clamped reduces the work of setting up the frame in the lathe to a fraction of that necessary were it to be chucked, and makes it easy to center the piece. The end of the frame has been bored ready for a ring bushing. The bushing is then bored to factory standard.

care of all the sizes of locomotive motors that the company uses.

A large motor field frame clamped on to a mandrel and swung in a lathe

being fastened in place by electric welding. This process requires that the frame be machined twice, once to bore out the worn part ready for the bushing and again to bore out the bushing to true center. This same procedure is followed in repairing worn axle boxes so that the standard size brasses can be used, but in this case the machining is done by a jig, in a horizontal boring mill. In the background of Fig. 1, can be seen on the ends of two motor cases, how the bushings are welded in place.

#### MANY MOTORS REPAIRED

An idea of the extent of this kind of work which is being done in the Library shops may be gained from the photograph, Fig. 1. This is only part of a group of locomotive motors which have been repaired and have been placed in the stock room adjacent to the shop. Albert Hasson, shop superintendent, explained that these motor cases are complete with field coils, and as all parts are standard, they can be sent on short notice to any of the mines in exchange for frames which have given trouble and are to be sent to the shop for repair.

Such work as this cannot be done

**Fig. 1—Part of the Group of Spare Motors in the Storeroom**

When the motor of a mine locomotive gets into bad condition a repaired motor is sent out from the shop and the damaged one returned for repairs. After the motor is overhauled and any badly worn parts built up to standard, this motor goes into stock.

Fig. 3—Mandrel Used for Swinging Motor Case in Lathe

In the foreground is one of the five mandrels used in the central repair shop of the Pittsburgh Coal Co., Library, Pa. Just back of the mandrel can be seen the ends of two motor field frames which have been repaired. A large ring bushing has been inserted and fastened by electric welding.

economically anywhere else than at or near the mines; the cost of handling and shipping motor frames to distant points is prohibitive. Just as soon as

other companies start this kind of repair service for their electric equipment they will begin to reduce the number of armature burnouts.

### Simple Shear and Bender For Chute Plates

A handy little tool used about the shop is the combination punch and shear pictured in Fig. 1. The stand is a home-made affair. Some pipe, some

Fig. 1—Boltless Stand

Here is the home-made stand upon which is mounted the punch and shear. The frame structure was welded together in a short time.

angle iron, bars, and a welding outfit were the only material necessary. Two pieces of pipe were cut to length, then heated and flattened for a short distance in the middle. They were bent so that when placed in position the legs had a good, stable spread. The two pipes were held in this position, properly spaced at the top, with reference to bolt holes already cut, and shear punch mounted. Thus a strong base was made in about an hour.

The apparatus partly shown in Fig. 2 is a home-made sheet bending machine which will make any internal angle from 30 to 130 deg., and is the product of the ingenuity of the managers of this sheet metal shop and the flexibility of welding processes. The shop had received a rush order for some rectangular tanks. Neat bends must be made in wide sheets. Inquiry was made for a sheet bender, but it

could not be delivered for three weeks. This was almost as long as the time allowed for delivery of the tanks.

In this dilemma it was decided to make a bending machine at home. After about two days' intermittent work, the machine illustrated was produced. It consists of three 6x6½-in. angles mounted on a welded pipe frame. The sides of the angle legs, which come in contact with the sheet, are faced.

The back or base angle is welded to the frame; the top angle closed to 30 deg. and suspended in vertical bars at each end. That is to say, a bolt is secured in a piece welded into each end of the angle. This bolt passes through a slotted hole in a vertical bar attached to the pipe frame, and ends in a disk to which a handle is fastened. This disk also has a pin set in it off center, which projects into the vertical bar and acts as a fulcrum. Thus, when the handle is moved, the angle is lifted or lowered to pass or lock a sheet between it and the base angle.

The third or bending angle is hinged back to back with the base angle. It

is trussed, as shown in the illustration, and is equipped with handles by which it can be rotated.

The bending apparatus is shown in position ready for the insertion of a sheet. When the line of bend is directly above the heel of the base angle, the upper one is lowered and clamped down to the sheet, then the bending angle is swung up until the required bend has been made.—*Oxy-Acetylene Tips.*

Fig. 2—Welded Parts for Bender

All mining plants at some time or another must replace chutes or screens. Some think it is difficult to shape sheet-iron, but here is a machine made at the mines which makes the work easy.

### Fan Exhaust Supplies Heat For Wash Water

At the O'Gara No. 12 mine near Harrisburg, Ill., exhaust steam from the steam-driven fan is used to heat the wash water in the bath house.

The complete housing and airway of the fan is constructed of concrete. At the end of the fanhouse is a large steel tank into which the exhaust from the steam engine discharges. Water, supplied from a reservoir nearby, circulates through this tank and is thus warmed. The heated water is then conducted to the wash room.

The method of heating is similar to that used in many boiler plants for heating feed water. Fans, being the most continuously operated machines around a coal mine plant, consume much power and therefore savings effected by devices attached to fans quickly mount into large figures.

Water-Heating Tank Conserves Wasted Energy

Wash water for the bathhouse is heated at the O'Gara No. 12 plant by the exhaust from the fan engine. Warm water is always available because the fan operates continuously.

# Production And the Market

## Seasonal Lull Hits Bituminous Coal Market; Caution Marks Anthracite Trade

Snappy weather throughout a large portion of the Middle West has injected some much needed vim into the steam coal business of that locality though domestic demand is somewhat slow when considered in relation to output. Trade in the Southwest also shows some improvement with a dip in the temperature. Little of outstanding interest marks the trade in other sections, which is of a spotty character, varying from minor gains at Pittsburgh to sagging tendencies in Kentucky. Indifference seems to be the attitude in Ohio, Atlantic seaboard and New England markets. On the whole the industry apparently is suffering from a seasonal lull that seldom fails to appear at this time of the year. The real unsettling element, of course, is the closing of lake navigation.

About the only feature of strength in the market is in screenings, which are in somewhat limited supply with consequent firmness in price tendency. The dearth is not due to any growth in demand, however, but is merely the natural corollary of the curtailed call for lump. Monthly government surveys of industrial conditions continue to show increased employment in most sections, save in New England, where the situation is not changing much.

### Moderate Demand for Anthracite

Demand for hard coal is marked by extreme caution, orders being fitful and in small lots. Yards are well stocked except for stove, the call for which is so steady that some operators are breaking down egg to keep pace with the demand for the more popular size. Chestnut also is quite strong, in some instances commanding the same price as stove. Egg and pea are in difficulty, however, some producers sending pea to storage piles.

Steam sizes are rather quiet, especially buckwheat No. 1; rice and barley are somewhat more active. With the falling off in demand it is probable that but for the curtailment of output by outlaw strikes there would be a softening in independent prices.

Within the last few weeks more than 5,000 mine workers have sailed from New York for their native lands to spend the holiday season and in many instances the entire winter months. It is expected that before the year ends the number will have been increased to nearly 10,000 mine workers and their families.

Coal Age Index of spot prices of bituminous coal has taken another tumble, standing on Dec. 15 at 169, the corresponding price for which is \$2.04, compared with 171 and \$2.07 respectively for the preceding two weeks.

### Hampton Roads Dumpings Heavy

Another marked increase in activity took place at Hampton Roads, dumpings of coal for all accounts during the week ended Dec. 11 totaling 479,099 net tons, surpassing the high mark of the previous week by 43,377 tons.

Bituminous coal production advanced substantially during the week ended Dec. 6, when, according to the Geological Survey, 10,612,000 net tons was produced. This was an increase of 972,000 tons—as shown by revised figures—over the preceding week, when operations were curtailed by the observance of Thanksgiving Day. Incidentally this was the fourth consecutive week in which output exceeded that of the corresponding week of last year. Anthracite output also turned upward after the holiday, the total for the week ended Dec. 6 being 1,814,000 net tons, compared with 1,611,000 tons during the previous week.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
Nov. 22.....	10,160,000	10,559,000

Cal. yr. to date (c)...	17,150,000	8,938,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Screenings Stiffen

Slow domestic demand in proportion to the available production has caused a strengthening of the steam market in the Midwest. Central Illinois fine coal has advanced to \$1.75, which gives it an edge over the higher grade southern Illinois screenings because of its short rate to the great consuming market in Chicago. Southern Illinois 1½-in. coal brings an average of \$1.60 and 2-in. about \$1.75.

The weather throughout the central region is snappy, running to bluster, but this has induced very little domestic business in most territories, at the same time increasing the tendency to produce coal. This combination has nearly broken down circulars on lump and egg, but hope for immediate cold weather staved off this calamity. The unsettled freight rate situation from the East to the Northwest causes a good deal of uncertainty in the market for Illinois and Indiana coal in Wisconsin and Minnesota.

Southern Illinois egg is hard to move and nut is worse, and the poor working time in the last couple of weeks has put all mines behind on their screening business. Mines that had been getting two and three days a week are doing better now, but they are piling up coal hoping for a cold wave. Strip mines continue to do well. Cars are plentiful, movement good and railroad tonnage fairly good. In the Duquoin-Jackson County field conditions are somewhat similar to those in the Carterville district excepting that coal is not moving as freely and working time is not as good.

The quietness that has prevailed in the Mt. Olive field was broken this week with the movement of domestic coal. Some of this is moving to the Northwest and some locally, while steam is moving to Chicago. In the Standard field there is little activity. A little coal is always moving but large volumes are on hand and prices are about cost or below. Mines are getting from one to three days a week. Railroad tonnage is light and pessimism covers the field. The only thing in this district that shows any change is screenings, which range from \$1.10 to \$1.25.

In St. Louis a little cold weather and a little more demand, principally for the middle grades of coal, is all that can be reported. There is practically no demand for anthracite or smokeless and coke is just a trifle better. Cold weather, of course, forces the poorer classes to buy coal and this usually is Standard, but this business is not in the volume that would be expected. Dealers' yards are all loaded. Local wagonload steam is good. The trucking of coal over the Free Bridge from East St. Louis is now under way in order to overcome a 45c. differential rate in the freight rate of coal from East St. Louis. This movement is still small but threatens to grow.

### Kentucky Prices Sag

Last week saw the weakest coal market in many weeks in Louisville, demand being light and offerings heavy. Screenings are holding firmly due to reduced production of prepared sizes in both fields. The small prepared sizes that

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

Index	1924			1923
	Dec. 15	Dec. 8	Dec. 1	Dec. 17
Weighted average price	169	171	171	181
	\$2.04	\$2.07	\$2.07	\$2.19

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

are moving for steam use are holding fairly well, but block, egg and lump are all weaker. Considerable distress coal is in various markets and a lot of "no bill" coal is on track in the coal fields, and some operators who have overproduced are on the verge of shutting down. Others are offering ridiculously low figures in an effort to force movement.

There is much undercutting of circulars. For instance, it is reported that some of the large producers in western Kentucky were so overloaded with unsold coal within the past few days that in some instances 6-in. block was shipped on high grade mine run orders at \$1.75 a ton, and mine run in some instances was shipped on nut and slack orders. The block market while quoted at \$2.25@2.50 is weak as a result of block being offered as low as \$2@2.25. Lump is offered at the latter figure, but egg has been in better demand and is quoted at \$2.10@2.35, with nut at \$1.50@1.85 and mine run, \$1.35@1.75. Screenings are \$1@1.25.

In eastern Kentucky a few specialty coals are quoted at \$3@3.25 and perhaps higher, but the block market is \$2.50@2.75 on good grades, with lump \$2.25@2.50; egg, \$1.75@2.15; nut, \$1.60@1.90; mine run, \$1.35@1.60 and screenings, 85c@1.10.

### Northwest Trade Is Fair

Navigation, as far as coal is concerned, closed officially Dec. 10 at the Head-of-the-Lakes. In all, 30 cargoes arrived during the last week, of which one was hard coal. In the receipts were several cargoes of Pocahontas, which puts this coal again on the Duluth market. Official figures of receipts during November show that 1,186,790 tons of soft and 67,434 tons of hard were received. This brings the

receipts for the season up until Nov. 30 to 1,264,705 tons of hard coal and 7,541,453 tons of soft coal.

Stocks on docks at present are estimated at 7,500,000 tons of soft coal and about 800,000 tons of hard coal. The normal consumption between now and the opening of navigation usually is about 5,000,000 tons of soft coal. Figuring this way, there will be plenty of soft on the docks at the opening of navigation. The anthracite outlook is far from bright, as consumers are burning anything but hard coal. Shipments from the docks last month were the heaviest in two years. In all 28,755 cars went out as against 26,415 in October, and 27,696 in July, 1922, which was the largest previous month. Docks are working overtime and some of them on Sunday.

Movement of coal from the docks in Milwaukee is only fair. The weather has spurred consumers a little, but there will be no rush for fuel until real winter cold waves send the temperature down to zero and below. Four cargoes of coal are now upward bound for Milwaukee. Their arrival will mark the close of the season for cargo coal. The receipts for December up to and including the 10th were 28,900 tons of anthracite and 85,668 tons of bituminous coal—a total of 114,568 tons. The receipts for the season up to the 10th were 805,862 tons of anthracite and 2,587,023 tons of bituminous coal—3,392,885 tons in all. The receipts of cargo coal in 1923, up to Dec. 11, when the season closed, totaled 966,224 tons of anthracite and 3,238,722 tons of bituminous coal—4,204,946 tons in all.

### Western Trade Improves

A little cold weather through Kansas and Oklahoma in the last week has reduced the surplus of domestic grades at the mines and has slightly improved operating time in the Southwest. But several weeks of cold will be necessary to bring production up to normal for this time of year. The improvement is not yet sufficient to eliminate shading.

In Colorado the cold weather which has prevailed for the past several days has naturally stimulated the market, particularly for lignite. There has been a slight improvement in the market for Colorado coals in Nebraska, Kansas and South Dakota. This has resulted in increased production and the mines are now operating at about 70 per cent.

The prevailing prices on the lignite coals in northern Colorado are \$3 for Weld County and \$4.25 for Boulder County. Southern Colorado bituminous is \$5.25 for lump, \$4.25 for nut and \$3.50 for pea (washed). Prices in the Dawson-Raton district, New Mexico, are: Domestic lump, \$4.50; nut, \$4; egg, \$4.50; pea, \$3.50. Coke prices for Dawson, New Mexico, are \$6, \$7.50 and \$8.75; for Colorado (Minnequa Segunda), \$6@7.50.

In spite of the heavy snowstorms in Utah working time at the mines has not increased appreciably, being still around 60 per cent of capacity. Stocks are much below normal. Dealers report a brisk demand for pea coal and slack for heating. All other sizes are in only fair demand. Railroads are taking very little coal now. Most of them are picking up their stocks. The metal industry continues to be the best industrial customer for coal.

### Spirits Flag in Ohio Markets

Fairish winter weather has failed to revive the flagging spirits of the Cincinnati market. "Free coal" is becoming increasingly hard to move and a clutter of "no bill" cars at the yards of originating railways has added to the gloom. Retailers are inclined to hold off from purchases rather than carry such stocks in their inventories at the close of the year. Prices on bituminous have a broad range, one large West Virginia company with mines in Logan County having cut under \$2, though specialized coals from Coal River, Elkhorn and Perry County are being sold as high as \$4 a ton for domestic block and 4-in. lump. Egg is a drug on the market, but mine run shows slight price variation. Nut and slack and smaller sizes of resultant also hold up well. The smokeless market is suffering from inertia following the closing of the lakes. River business is booming with the stage holding at a good depth.

Trade at Columbus continues spotty. Domestic business is still slow due to continued unfavorable weather in many localities. Retail stocks are generally heavy and dealers are slow in placing orders. Many are making extremely low quotations to reduce stocks. The so-called fancy grades are in best demand, although the edge is off the Pocahontas market. Steam business is dull and featureless. Considerable demurrage coal, particularly in Toledo and Detroit,

has affected the Columbus market. Reserves are good and in some cases consumers are using these in preference to buying on the market. Overproduction of steam grades appears to be the main factor.

At Cleveland there is a scarcity of slack and nut-and-slack, which have stiffened 5c. to 15c. per ton during the week. Apparently many steam consumers failed to lay in reserves in these grades when the supply was plentiful, consequently, with the production of lump considerably off and the demand for slack stronger at this season of the year than is ordinarily the case, it is freely predicted that spot prices on these grades will continue to advance. Inquiries from steam consumers, other than for these grades, continue to be negligible because of hand-to-mouth buying.

### Nominal Gain in Pittsburgh Market

The Pittsburgh market shows a slight gain in tonnage turnover and slightly increased irregularity in prices, but broadly speaking there is no substantial change. Small lot inquiries in the spot market are more numerous but prices are not quotably changed except that steam slack now brings \$1.10@1.20 against a flat price of \$1.10 formerly quoted. The steel industry is running at a considerably better rate, but that does not seem to help steam coal.

The situation at Buffalo is not improving much, except that the feeling is better. Scarcity of slack has brought up the price about 20c., but that is merely because so little lump is selling that slack is scarce. There is some improvement in business generally and it looks as if by the first of the year the demand for soft coal would be considerably better. Non-union mines are practically furnishing the coal. The lake trade is at an end, with shipments of 2,616,550 tons, as against 2,907,320 tons the previous season.

### Only Casual Demand in New England

The New England market shows little change. Steam coals are in ample supply and there is only casual demand for relatively small tonnages. Inquiry for spot shipment in cargo lots is light, and about the only opening for tidewater coal is for distribution inland from ports like Boston, Providence and Portland. The industrial situation does not improve, although there are textile and shoe manufacturers who look for better business early in 1925. Generally, the steam grade is dragging on the bottom with prices in most quarters at the lowest point of the year.

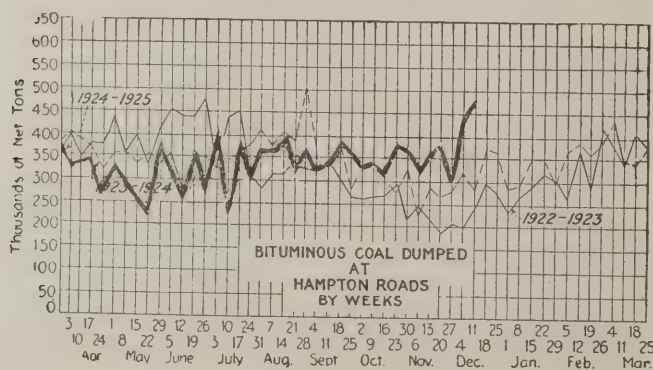

At Hampton Roads there continue to be fresh accumulations that the agencies are canvassing this territory to sell. The range is \$4@4.25 per gross ton f.o.b. vessel for smokeless coals, the actual price depending upon mine origin and the reputation of the coal.

All-rail from central Pennsylvania there is nothing more than the current moderate request that has been characteristic for several months and prices are on the same minimum basis. Most of the tonnage coming forward by water from New York and Philadelphia piers is restricted to specialties, including coal for gas producing, the quantity of ordinary steam coal moving in these channels being very small.

Prices on cars Boston at the rehandling wharves are wavering from \$4.25@4.35 per gross ton. Those factors who lack unloading facilities of their own are hard put to it to dispose of current arrivals and at the same time keep coal coming forward.

### Lull in Atlantic Seaboard Markets

Buyers are taking but little interest in the coal market at New York, though a few days of seasonable temperatures last week did create a little better demand for spot coal.

There have been no changes in quotations. Operators and shippers continue to evince optimism that business and prices will be better after Jan. 1. More contracts are expected to be closed than were closed this year. Demand for tidewater coal is dull, but the tonnage coming forward is moving with little pressure.

Wheels of industry at Philadelphia are going at a pretty fair speed, and while the average coal buyer is inclined to lessen purchases with the approaching end of the year, there is much new business being placed. The best demand is for the higher grades of Pennsylvania low volatiles. Gas slack is in limited supply.

At Baltimore the demand for soft coal has continued about on the average of the past three or four months. Industrial buyers are taking in small quantities as needed. The export situation continues dull, although the first 12 days of December showed a marked improvement over the corresponding period of November.

Domestic trade is practically flat at Birmingham, awaiting weather favorable to renewed business in the wholesale line. There is no material change in the steam market over a week ago. Fairly heavy rains last week probably will enable hydro-electric power plants to curtail operation of steam standbys, which have been heavy consumers of coal during the long drought. Railroads and other contract consumers are taking a little more coal, but are said to be already fairly well stocked against holiday interruption. Buying of commercial fuel is still restricted largely to immediate needs.

### Anthracite Trade Unsteady

Unsteadiness characterized the anthracite market at New York last week. Orders were less plentiful and it was the belief in some offices that but for the outlaw strikes in the coal fields the lessened demand might have reduced independent prices. Stove coal continues to move steadily and the demand is so strong that several operators are breaking down egg in order to meet the demand for the smaller size. Chestnut is gaining strength and in several instances is quoted at the same price as stove size. Pea is troublesome to move and is being sent to storage by some operators. Buckwheat No. 1 is slow but rice and barley are fairly active.

Philadelphia consumers are buying cautiously, as 90 per cent of all orders received are for single tons. Yards are well stocked except for nut, for which there is a steady call. There have been no further price increases. Egg and pea are causing trouble and steam sizes are rather slow.

Hard coal men at Baltimore report only a moderate demand, mainly due to the remarkably open weather. Many consumers who ordinarily begin to run out of coal about this time are still running along on the light supplies already laid in. The exhibit of devices arranged to burn buckwheat coal is to open in a few days.

Trade at Buffalo is as dependent on the weather as it is with winter going out and the prospect is that the trade will be in a slow-go-easy way all winter. There is talk of more advancing of price, supposed to be on account of the cost of the many strikes that have beset certain districts, but the consumer pays little attention to it.

## Foreign Market And Export News

### British Market Develops Strength; Idle Pits Resume

Renewed strength has appeared in the South Wales coal market, steady improvement and material reduction of stocks being in evidence. Several pits are resuming operations after three months of idleness.

Interest is chiefly centered in business for the early part of next year. Most collieries are well booked over December, but January bookings are only moderate. There is a fair demand for large steams, and small steams have improved.

Coal depot exporters have booked 250,000 tons of second Admiralty large over 1925 at 25s. to 25s. 6d. f.o.b., and the Admiralty has placed contracts aggregating 350,000 tons of second and best large steams at from 26s. to 27s. The Egyptian State railways have contracted for 200,000 metrical tons of Monmouthshire large steams for de-

livery beginning January to May, at 34s. 8d. to 34s. 11d. c.i.f. Alexandria has placed a contract for an equivalent amount at 24s. to 24s. 3d. f.o.b.

The general tone of the Newcastle market has improved, general inquiry being quite satisfactory, especially for gas and steam coals. Best steams are now being sold ahead for delivery next year for 19s. f.o.b. Around 70,000 tons of Durham gas coals have been sold to Italy and Sweden. Bunker coals are going better though they still glut the market. There is still considerable unemployment and short time.

Production by British collieries in the week ended Nov. 29, a cable to *Coal Age* states, was 5,303,000 tons, according to official reports. This compares with 5,309,000 tons produced in the preceding week.

### Foreign Trade Lightens Dullness At Hampton Roads

Business at Hampton Roads is dull, with demand for coastwise light and bunker trade only fair. A slight increase noted in foreign buying has proved a temporary stimulant.

Many mines have reported that they are preparing to shut down for the holidays, and the trade at Hampton Roads expects little improvement in business until the new year. Domestic retail business is suffering from unusually warm weather.

### Sluggish Tendency Prevails in French Coal Market

Inquiry for industrial fuels in the French coal market is slightly heavier while the house coal situation remains quiet. The mines, however, are shipping regularly on existing contracts. Because of lessened demand French importers are refusing any additional tonnage from Belgium for the moment.

On the other hand, arrivals from Great Britain are normal.

With regard to German commercial coals, the high prices asked by the Coal Syndicate have curtailed French buying. There are 5,000,000 tons of coal now lying in the Ruhr, and they will move only if the Germans quote reasonable prices. In order to find new outlets, they are now facilitating payments by allowing credit of three to six months.

The wage convention now in force in the Nord and Pas-de-Calais mine will end Dec. 31, and the labor unions have appointed a subcommittee to take up the task of obtaining higher pay for the mine workers.

From Nov. 16 to 22, France and Luxemburg received 117,800 tons of indemnity fuel, of which 36,600 tons was coal, 74,700 tons coke and 6,500 tons lignite briquets. Deliveries of Ruhr coke in November amounted to 174,138 tons, an average of 5,800 tons a day, compared with 8,500 to 9,000 tons previously. Receipts for the first three

days of the current month were 39,046 tons, a daily average of 13,000 tons. The price of indemnity coke is unaltered and presumably will remain so for some time.

## News Items From Field and Trade

### ALABAMA

The Franklin Coal Mining Co. is constructing a 400-ton Montgomery coal washery at its Powhatan No. 2 mine, in the western end of Jefferson County, which will give the company a capacity of 750 tons of washed coal per day from its two openings.

Among increases in capital stock of corporations reported by the Secretary of State is the Union Coal Co., Walker County, \$1,100,000. This increase in capital is in connection with the recent acquisition of about 15,000 acres of coal lands from the Sloss-Sheffield Steel & Iron Co., by A. B. Aldridge, of Birmingham, and associates. An increase of \$100,000 also is reported in the capital stock of the Goodwin Coal Co., Inc. of Dora, Walker County.

### ILLINOIS

Harry Tanner and Charles Law, of Pana, sold the Litchfield coal mine at Litchfield to John Puckett, of that city, for a reported price of \$60,000. Temple McDonald, of Hillsboro, has been named manager and will reopen the mine at once.

David Hagman and Grover Davis have formed a partnership to operate a new coal mine at Matherville.

Two mines in Springfield have been opened within the last few days. Empire Mine No. 1, owned by the Illinois Coal Co., has been opened with a large force. This is the old Jones and Adams mine east of the fair grounds. The Spring Creek Coal Co.'s mine west of the city on the Baltimore & Ohio Southwestern R.R. also has been opened with four hundred men working. A miners' train is being operated by the B. & O. S. W., from Second and Madison Streets, Springfield, to the mine. More than one-half of the thirty mines in the Springfield district will be in operation with the opening of these two mines. At one time during the summer only one-third of the mines were in operation.

G. W. Bower and son of Monett, Mo., with a company of men, are prospecting for coal near Pinckneyville. They are drilling south of that town where they have found coal within 18 ft. of the surface. They have forty tracts of forty acres each leased.

Mine No. 5 of the Spring Valley Coal Co., at Dalzell, has been permanently closed and sealed. The work of dismantling the mine will be begun at once. This mine was sunk in 1899 and was for several years considered one of the best of the Spring Valley Coal

Co.'s mines. The mine was closed Feb. 15, 1922, and since that time has been idle. The company also is closing its store at Spring Valley.

The Gano Moore Coal Mining Co., of Philadelphia, Pa., is about to purchase the properties of the defunct Southern Gem Coal Corporation of Illinois for \$2,000,000. The Philadelphia concern is said to have made the offer, and its acceptance depends upon the sanction of the federal district court in East St. Louis. A bond issue of \$1,175,000 and a miners' payroll of \$225,000 due more than a year ago are outstanding. There are various other claims against the properties totaling about double the \$600,000 which would remain of the purchase price of \$2,000,000.

### IOWA

The McCagg mine, east of Knoxville, has been closed, the last ton of coal being billed out to the Rock Island R.R., which has been one of the largest customers of the mine. The McCagg mine was one of the largest mines in Marion County, having employed as many as 150 men, who made their homes in Knoxville and Flagler.

### KENTUCKY

The U. S. Circuit Court of Appeals at Cincinnati held that the U. S. District Court at Jackson erred in refusing the Fordson Coal Co. a restraining order against W. J. Maggard, sheriff of Leslie County, and ordered the lower court to issue a preliminary injunction. The coal company had sought and been refused a restraining order against the sheriff from collecting more than \$11,797 taxes on its tract of 80,951 acres of land in Leslie County.

The Bulan Coal Co., Bulan, will soon begin erection of ten miners' cottages.

It is reported that a big coal merger is pending at Lexington for merging coal companies and coal properties in the Carrs Fork section of Eastern Kentucky. Companies mentioned as being interested in the deal are the Scuddy Coal Co., Montgomery Coal Co. and the Happy Coal Co. although President C. L. Ryley of the latter company denies it. It is claimed that if the deal is made a paper manufacturing concern of Providence, R. I., will take the bulk of the mine output.

Reports from the Whitesburg and Hazard districts of eastern Kentucky are to the effect that there has been a good deal of coal land leasing underway

and some new railroad construction is planned, one contract having recently been let. Much of the new development appears to be planned in the Carrs Fork Section above Vicco, on the Knott County border, according to reports. The fact that the Louisville & Nashville R.R. is to connect through that section with the Carolina, Clinchfield & Ohio, giving outlet to the South Atlantic, will materially improve traffic facilities in the district and enable operators to move coal more freely in times of good demand.

John W. Menzies, U. S. Court clerk at Covington, has gone to Prestonburg, in compliance with orders of federal court, as a special commissioner to sell the property, merchandise and equipment of the Liberty Coal Corporation in Floyd County. The sale follows the litigation in the case of T. H. Morris, trustee, against the Liberty Coal Corporation, which was filed in the federal court at Covington in November, 1922. The order of sale directs that the property shall not be sold for less than \$52,500. The land is divided into four tracts, all of which are located on the left fork of Beaver Creek in Floyd County.

### MINNESOTA

The Berwind Fuel Co. has started working on a third addition to its briquet plant at Superior, Wis. The addition will be ready in the spring. The necessity for increased capacity bears testimony to the popularity which this form of fuel has gained at the Head-of-the-Lakes.

W. H. Godwin, vice-president of the Carnegie Coal & Dock Co., was at Duluth-Superior harbor last week, inspecting docks. He spoke most optimistically of the future, and said that he did not anticipate any great surplus of stocks in the spring.

### NEW YORK

The Emergency Coal Board appointed by Governor Alfred E. Smith last year issued a report last week in which it assured consumers of coal that the coal situation is encouraging and that the supply is plentiful. "Information in our possession," said the board, "leads us to believe that there will be an ample supply during the coming winter. Should any emergency arise the committee stands ready to take command." The board members are General Charles W. Berry, George Eltz and Health Commissioner Monaghan.

## OHIO

With no opposition all officers of the Ohio district of the United Mine Workers have been elected for the coming year. They are Lee Hall, president; G. W. Savage, secretary, and William Roy, vice-president.

John H. Eagleson, a Columbus attorney, has been named receiver for the Starr-Jackson Mining Co. upon the application of Adam Penman, who claimed a debt against the company. The concern has been operating a small mine near Logan, in the Jackson field. Offices in Columbus had been discontinued for some time.

While the date has not been definitely fixed, the court has decided that the assets of the Maynard Coal Co., of Columbus, which has been in the hands of receivers for about a year, will be sold at auction about Jan. 5 next. Receivers Williams S. Harman and Frank L. Stein have been instructed to advertise the properties when the date is definitely fixed. The assets consist of working mines in the Pomeroy field in Ohio and in the Hazard field in Kentucky.

Operations have been resumed again at the Webb mine of the Cambria Collieries Co., south of Bellaire, employing about 600 men. It had been idle since about the middle of July owing to a disagreement between the miners and the company. At a recent meeting of the members of Local Union No. 1840 terms of the company were agreed to and men were immediately ordered out to work. During the time the mine was in idleness a good deal of machinery and equipment was added.

## PENNSYLVANIA

Unofficial returns from the biennial election of District No. 5, United Mine Workers (Pittsburgh) indicate the re-election of President P. T. Fagan, Vice-President W. J. Patton, Secretary-Treasurer William Hargest and all other officials seeking re-election.

Charles O'Neill, secretary of the Central Pennsylvania Coal Producers' Association, in a letter to the operators throughout the district, announces that no further action has been taken looking to an adjustment of the wage scale. Mr. O'Neill points out that with the resumption of work at a number of important operations where there are large unions which have repudiated the scale and allowed the men to return to work on the 1917 basis the situation will gradually adjust itself. He says the pressure of the movement among the miners who are without employ-

ment or money to support their families will bring about the solution of the problems facing the operators.

John Brophy, president of District No. 2, United Mine Workers (central Pennsylvania), with headquarters in Clearfield, was re-elected to that office at an election conducted throughout the district on Dec. 9. He had no opposition. The name of George Bassett, who had been nominated, did not appear on the official ticket. Richard Gilbert, secretary-treasurer, who has held that post for a quarter of a century, was re-elected without opposition. James Mark, the present vice-president, also was re-elected, he being the only one of the three with opposition.

Thirty employees of the Ebensburg Coal Co. at Colver, Cambria County, have organized to take the course in mining offered by Pennsylvania State College. W. G. Duncan, of the college mining department, organized the class, and the instructor in mining will be F. M. Maloy, while Thomas Brown will be the instructor in electrical work. The students will be awarded mine foreman certificates if they successfully complete the course.

The Shipman Coal Co., of Shamokin, has just closed a deal for the lease of a virgin tract at Maysville Park. The same firm is said to be dickering with the Lehigh Valley company for a lease on a tract close to the former's present operations, a royalty proposition having been suggested.

Local No. 4716, United Mine Workers, at Lilly, Cambria County, at a recent meeting adopted a resolution indorsing the action of the district officers in refusing to acquiesce in solicitations of the operators for a reduction in wages. The resolution sets forth that the local union believes that a reduction of wages is not the remedy for slack work.

James West, Sr., has just purchased 45 acres of coal in Luzerne township from the Superior Connellsville Coal & Coke Co. for \$77,514. All mining rights go with the sale of the land. The coal is said to be Pittsburgh 9 ft. coal. George Whyel is president of the Superior and transacted the deal with West.

Isaac Taylor, of Uniontown, is in the Presbyterian Hospital at Pittsburgh recovering from the amputation of his left leg above the knee on Friday, Dec. 5, on account of hardening of the arteries. He withstood the operation very well, especially considering his advanced age.

According to a report from Shamokin a deal is under way which will give the Madeira-Hill Coal Co. a lease on a

valuable portion of a tract owned by the Lehigh Valley Coal Co. between Johnson City and Kulptown. This tract is said to possess some of the richest seams in the anthracite region.

As a result of the decision of the U. S. Supreme Court upholding the constitutionality of the Pennsylvania anthracite tax, the state treasury will receive approximately \$6,000,000, held up by the litigation. In his biennial estimate of the expected revenues for the coming two-year appropriation period, Auditor General Samuel S. Lewis has figured \$12,000,000 as the revenue from the coal tax, or \$6,000,000 a year. The sum which will now be received has been included in his estimate which will guide the Legislature in making its appropriations during the coming winter.

The State Workmen's Insurance Board has authorized a dividend of 15 per cent in addition to the 10 per cent differential allowed in compensation insurance written with the state fund. The state fund has issued 8,500 new policies during the present year. The total reserve of the fund set aside to pay claims to injured workmen and to dependents of deceased employees of policyholders in the fund is \$3,140,661. This amount, the board announced, is exclusive of claim payments already made. During the past seven years the fund has accumulated a surplus amounting to \$2,362,609.

## UTAH

D. D. Muir, Jr., general manager of the United States Smelting, Refining & Mining Co., has been made vice-president and general manager of the United States Fuel Co., a subsidiary of the first-named corporation. This promotion comes to Mr. Muir but a comparatively short time after he was named second vice-president of the United States Smelting, Refining & Mining Co.

The National Coal Co., headed by F. A. Sweet, C. N. Strevell, C. T. Worley, George A. Storrs and George S. Payne, all of Salt Lake City, has petitioned the Public Utilities Commission for authority to construct 13 miles of railroad to connect the coal properties in the Gordon Creek Canyon district with the Utah Railway two miles south of Helper. The company proposes to build 10.627 miles of main line beginning at station 753 on the Utah Railway and extending in a northwesterly direction. At Coal Creek, according to the plans submitted to the commission, one branch would extend 1.375 miles into the Coal Creek district, while the main line would continue for a few miles, where a branch 0.527 mile long would extend in a northwesterly direction to open up the Right Ford properties. Another branch would extend 0.546 mile into the Bryner Canyon district. Applications covering the necessary rights of way have already been filed with the U. S. Land Office. It is set forth that thousands of acres of new coal lands would be opened by the branch line. The proposed line is to be a coal road exclusively. If permission to construct the line is granted the work will be commenced at once, it is stated.

### Anthracite Economy Service Traveling Show

To teach people how to cut down their coal bills the Anthracite operators are sending this unique traveling information bureau and exhibit throughout the country this winter.

## VIRGINIA

The Island Creek Coal Co., of West Virginia, is preparing to open a branch office in Norfolk within a short time. No announcement has been made as to who will take charge.

The Fort Dearborn Coal Co., has changed its name to the Fort Dearborn Fuel Co., Inc., authorization having been given by the State Corporation Commission this week for the change. C. Henry Harman is president of the company and W. G. Brinson is in charge of the Norfolk branch.

## WEST VIRGINIA

Permission has been granted to the Preston Smokeless Coal Co. to increase its capital stock from \$75,000 to \$100,000.

Plans have been matured by the Gauley Mountain Coal Co. to develop a tract of 4,000 acres of coal land on Maple Meadow Fork of Coal River, in Raleigh County, which in recent tests by diamond drill showed the existence of the Beckley seam of smokeless coal. The Hewitt and other New York interests own the Gauley Mountain Coal Co., of which R. H. Morris, of Ansted, is the resident manager.

Five coal tracts in the Liberty district of Ohio County were purchased early in December by S. A. Williams from Lee Grossman and others for \$42,500. Coal and farm property on the Middle Wheeling Creek road at the same time was acquired by three Elm Grove men for \$36,000, the coal purchased being in the Pittsburgh vein.

The Coalfield Fuel Co. and the West Virginia Eagle Coal Co. announce the removal of their offices from the Virginian Land Bank Building, Charleston, to their mines at Boncar, Fayette County.

Deputy sheriffs and state police have arrested 16 men charged with conspiracy to blow up the tippie of the New England Fuel & Transportation Co. at Grant Town. Some of the men have been released under bond of \$1,000 for the next term of the grand jury. The arrests were made by Sheriff John D. Charlton of Marion County upon information received from passengers on a street car running between Fairmont and Fairview who say they heard 16 men discussing the alleged plot to dynamite the tippie.

Fire at the plant of the Donald Coal Co. at Stollings, early in December, destroyed seven miners' dwellings and made six families homeless. None of the plant buildings, however, was damaged by the fire.

Whatever may be the outcome of court proceedings in southern West Virginia believed to be indirectly related to the question of unionizing the mines in certain fields where there has been no organization, mine owners in the Kanawha field are still proceeding against union miners occupying company houses. A large number of deputy sheriffs have been engaged for the last week in evicting striking miners, 35 families having been ousted from the houses of the Bellemont Coal Co. at

Crown Hill and about 66 families from the houses of the Campbells Creek Coal Co. on Campbells Creek. Both companies declined to sign an agreement with the union and have made arrangements to operate non-union.

Fire early in December at the plant of the Guyan Mining Co. at Wilbur caused a loss of approximately \$150,000, partly covered by insurance. The headhouse, tippie, conveyor and much other outside plant equipment was totally destroyed, forcing a suspension of operations for the time being. It is believed that the plant will be rebuilt just as soon as possible though just what the plans of the company are has not been stated by the general office at Cincinnati.

The Island Creek Coal Co. has declared an extra \$1 a share on the common stock, besides the regular quarterly dividend of \$2, both payable Jan. 1 to stockholders of record Dec. 19. Three months ago a similar extra dividend was declared. The regular quarterly  $1\frac{1}{2}$  per cent on the preferred also was declared. It is payable on the same dates as the common dividends.

## CANADA

T. W. Scott, chief engineer for the Canadian Collieries (Dunsmuir), Ltd., has been appointed assistant superintendent for the Cadomin Coal Co., Alberta. Fellow members of the Canadian Collieries staff tendered Mr. Scott a dinner and presented him with a Brunton pocket transit.

The Campbell Commission, appointed by the federal government under the Combines Investigation Act, which has been sitting at Winnipeg for some time to inquire into dealings of the Winnipeg Coal Dealers Association, will continue its sittings at Brandon, Manitoba; Saskatoon, Saskatchewan; and Calgary, Alberta.

The Rothwell Coal Co., Avon Coal Co., Harvey Welton and Welton & Henderson Co. have submitted a petition to Sir Henry W. Thornton, general manager of the Canadian National Railways, asking that a spur line of that system be built to the southern mining area at the Grand Lake coal fields. It was promised that consideration would be given this matter. There is a spur line in the southern area but it is from the Grand Lake Coal & Ry. line. Recently the Canadian National built a spur line extending from the transcontinental line across Canada from Moncton to Prince Rupert, connecting with the new northern area developed in the Grand Lake territory. W. B. Evans, manager of the Rothwell Coal Co., presented the petition.

Nearly one thousand miners of the Edmonton District Miners' Federation have joined the Central Council of the Canadian Labor Party following a mass meeting held recently at Beverly.

Reports from the Drumheller field, Alberta, indicate that production has reached a high level, no less than 322 cars passing over the Canadian National Ry. weigh scales in one day recently. The mines are striving to fill

their back orders, but cold weather has deluged them with more business, and the prospects are that it will be some time before they are back to normal. The total shipments for the week ending Nov. 22 were 1,862 cars, as compared with 1,688 cars in the previous week.

W. H. Sutherland, provincial Minister of Public Works, has announced that the government has set aside \$15,000 to be used for road work in the Fernie district, which is to be started at once, with a view to relieving distress among the miners thrown out of work by the closing of the Crow's Nest Pass Coal Co.'s Coal Creek collieries. Charles Stewart, Federal Minister of Labor, who had been asked by the provincial government to co-operate in finding work to relieve the distressed miners, has stated that his department cannot do anything.

According to figures just made public at Ottawa, there have been 145,000 tons of Nova Scotia and New Brunswick coal shipped into Central Canada under the system of bounties amounting to 50c. per ton, established by the Dominion Government on Sept. 2. Of this quantity 28,000 tons went to Ontario and 117,000 tons to Quebec.

## New Companies

**Wilputte Coke Oven Corporation**, Louis Wilputte, president, Augusta, Me., chartered under Maine laws, has filed a certificate of statement and designation in the office of the Secretary of State at Albany, N. Y., to enable the corporation to do business in New York State. The corporation will manufacture coke and gas products and is capitalized at 1,000 shares of no par value. The New York office is 469 Fifth Avenue, New York City.

**The Texas Coal & Mining Co.** has been incorporated in Eagle Pass, Texas, with a capital stock of \$50,000, by C. W. Settle, R. E. Doty and T. J. Evers.

**The Lincoln Coal Co.**, with a capital stock of \$50,000 has been organized in Erie by James Brennan, P. H. Powers, Thomas P. Morgan and T. Woodbury. It is understood the new company will take over and operate a mine, but the directors will not reveal their plans.

The Kansas State Charter Board recently granted a charter to the **South End Coal & Mining Co.**, of Mineral, Kan. The incorporators were Dug Murphy, George Dixon, Tom Young, Bert Hardesty and Joe Frye, all of Mineral. The company is employing forty men in its mine south of Mineral, and expects to increase its payroll soon. The mine, which formerly was operated by the Smith Coal Co., was abandoned several years ago because of faults, but a year ago the men responsible for the new company cleaned up, and since breaking through the fault have been operating it profitably.

A charter was granted recently to the **Englevale Coal Co.** of Frontenac, Kan., by the Kansas State Charter Board. The company, incorporated at \$100,000, has for its president J. S. Patton, and S. I. Patton is its secretary. The announced purpose of the company is to separate the Patton properties near Englevale from the Patton Coal & Mining Co., which operates near Frontenac.

**The Rodgers-Elkhorn Coal Co.**, capital \$50,000, was formed recently for development on 1,000 acres of coal property in the Shelby Creek section of the Pike County border, in eastern Kentucky. T. T., T. F. and G. E. Rodgers, all of Cincinnati, are the men behind the new organization.

A state charter has been issued at Harrisburg, Pa., to the **Hickory Run Coal Co.**, Wilkes-Barre, with a capital stock of \$25,000. The purpose of the company is to mine and ship coal, and the incorporators are: Nat D. Stevens, Tunkhannock, Pa., treasurer; W. D. Phelps, Forty Fort, Pa., and H. M. Reber, Wilkes-Barre, Pa.

## Traffic

### Raise in Coke Rates Denied

It was reported from Washington on Dec. 8 that the Interstate Commerce Commission had refused to approve the proposal of several railroads to increase freight rates on coke from \$2.59 to \$2.90 a ton in car lots from Kentucky, Virginia and Tennessee producing points to Cincinnati, Covington, Newport and vicinity adjacent to Cincinnati.

## Association Activities

The Montreal Coal Association, Inc., has been organized by the wholesale and retail coal dealers of Montreal with the object of putting a stop to malpractices in the trade, more especially the giving of short weight. The association has obtained a provincial charter of incorporation. The following officers were elected: President, R. J. Buck, president of the George Hall Co., of Canada; vice-president, Emile Cool; secretary, Charles Petrie; directors, L. Z. Cohen, L. E. Barrett, L. T. Vipard, D. L. Campbell, H. Aird, J. O. Labreque, J. O. Charlevoix, C. E. F. Dumaresq and G. P. Morgan. The association has a membership of about 100, including nearly all the wholesalers and a large percentage of the retailers.

R. C. Tway, of the R. C. Tway Coal Co., Louisville, operating mines in Harlan County, was re-elected president for the sixth consecutive term of the Harlan Coal Operators' Association, at the annual meeting at Harlan, Ky., Nov. 19. B. W. Whitefield, Sr., of Harlan, was named vice-president, and E. R. Clayton, Harlan, re-elected secretary. The report of the association showed forty-three members, representing an investment of \$25,000,000, and last year these members produced 3,878,008 tons of coal. The Louisville & Nashville R.R. furnished a special train for a trip of inspection over the Harlan district in the afternoon for members and their families. The annual dinner was held in the evening, at which time Harry L. Gandy, Washington, executive secretary of the National Coal Association, was the principal speaker.

## Publications Received

**Annual Report of Coal Mines, State of Alabama, 1923, Including 1922 statistics.** Pp. 160; 6x9 in.; tables.

**Natural Gas in Alberta,** by R. T. Elworthy, Mines Branch, Department of Mines, Ottawa, Canada. Advance section report on Mines Branch investigations of mineral resources and the mining industry during 1923. Pp. 35; 6x9 in.; tables.

**Permissible Explosive, Mining Equipment and Apparatus Approved Prior to Jan. 1, 1924,** by J. E. Crawshaw, L. C. Hsley, D. J. Parker and A. C. Fieldner, Bureau of Mines, Washington, D. C. Technical paper 364. Pp. 30; 6x9 in.; tables.

**Seasonal Operation in the Construction Industries: The Facts and Remedies.** McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City. Pp. 213, 6x9 in. Price, \$2.50. Reports and recommendations of a committee of the President's conference on unemployment, with a foreword by Herbert Hoover.

**Engineering in American Industry—The Development of Industry in these United States during One Hundred and Twenty Years,** by Conrad N. Lauer, McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City. Pp. 96; 9x12 in.; illustrated. Price, \$2.50. The book presents in interesting style, by means of text, old pictures, graphic charts, historical and statistical data, the story of the growth of industry and engineering.

**Labor Relations in the Fairmont (W. Va.) Bituminous Coal Field,** by Boris Emmet, Bureau of Labor Statistics, Washington, D. C. No. 361. Pp. 86; 6 x 9 in.; tables.

**A. S. T. M. Tentative Standards, 1924.** American Society for Testing Materials, Philadelphia, Pa. Pp. 763; 6 x 9 in.; illustrated. Price, \$7 in paper and \$8 in cloth binding. Tentative standards for the following are given: Coal and coke, timber, preservative coatings, insulating materials, petroleum products and lubricants.

**The Organization and Functions of the Institute of Research of Lehigh University,** Bethlehem, Pa. Circular No. 1. Pp. 19; 6 x 9 in. Describes the organization and functions of the institute.

**Eye Hazards in Industrial Occupations,** by Louis Resnick and Lewis H. Carris. The National Committee for the Prevention of Blindness, Inc., New York City. Pp. 247; 6 x 9 in.; illustrated. Price, paper bound, \$1.50; fabrikoid, \$2.50. A handbook for safety engineers, safety inspectors, etc.

**Annual Report of the State Inspector of Coal Mines of Arkansas.** Pp. 48; 6 x 9 in.; tables.

**Annual Report of the Board of Regents of the Smithsonian Institution,** Washington, D. C. Publication 2724. Pp. 554; 6 x 9 in.; illustrated. Includes operations and condition of the institution for year ending June 30, 1922.

**Employee Representation Plan; Policy-holders Service Bureau, Metropolitan Life Insurance Co., Madison Ave., New York City.** Report No. 67. Pp. 26; 8x11 in. Summary and brief analysis of employee representation plans recently developed in American industry.

## Industrial Notes

**The Nordberg Manufacturing Co.,** of Milwaukee, Wis., which has for many years constructed hoists, oil engines and compressors, expects to enter in the business of manufacturing underground shoveling machines, a special department having been opened for that purpose.

**The Conveyors Corporation of America,** Chicago, Ill., announce the appointment of C. S. Price, First National Bank Bldg., Hazleton, Pa., as its district representative for northeastern Pennsylvania. Associated with Mr. Price in the sale of the American steam jet ash conveyor is E. E. Elliott, who has had wide experience in steam jet ash disposal engineering.

## Obituary

**T. S. Neel,** aged 60, a prominent coal man of Johnstown, Pa., died suddenly at the home of his brother in Huntington, W. Va., early in December, while on a business trip. He is survived by his wife and two children of Johnstown, Pa., and two brothers, James Neel, of Highcoal, W. Va., and W. S. Neel, of Huntington. Both of Mr. Neel's brothers are engaged in the coal business.

**Thomas F. Kelly,** of Coalport, one of the leading operators in the Clearfield district of central Pennsylvania, died at the Jefferson Hospital, in Philadelphia, Dec. 7, aged 51 years. He was head of the Irvona Coal & Coke Co. He is survived by his wife and nine children. Burial was made at Snow Shoe on Dec. 10.

## Coming Meetings

**American Engineering Council.** Annual meeting Jan. 16-17, 1925, Washington, D. C. American Engineering Council, 29 West 39th St., New York City.

**Northeast Kentucky Coal Association.** Annual meeting Jan. 22, 1925, Ventura Hotel, Ashland, Ky. Secretary, C. J. Neekamp, 816 Ashland National Bank Bldg., Ashland, Ky.

**American Institute of Electrical Engineers.** Midwinter convention, Feb. 9-13, 1925, 29 West 39th St., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**American Institute of Mining and Metallurgical Engineers.** Annual meeting, Feb. 16-19, 1925, 29 West 39th St., New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

## New Equipment

### Amperehour Meter Takes Bumps and Jolts

The Sangamo meter, recently placed on the market, is designed for installations where the well-known Sangamo locomotive type meter has previously been specified—on electric automobiles, trucks, mine locomotives, industrial tractors, etc., where severe conditions of operation are likely to be encountered.

Installed on the vehicle, truck or locomotive, the meter indicates, by means of a black hand, the amount of battery discharge that has taken place. By

**Amperehour Meter with Non-Spilling Mercury Element**

Moisture is effectively excluded so that the formation of mercury dross is retarded.

comparing the position of this hand with a red hand located at the point where the battery should be recharged, the operator can always tell what remaining capacity is available before the battery should be put on charge. This guards the vehicle from being stalled in service.

When the vehicle is placed on charge the amperehour meter automatically gives the battery the required overcharge and opens the charging circuit at the proper time, thus eliminating the need for attendance.

The meter operates on the mercury motor principle and is extremely simple in construction. One set of permanent magnets furnishes both the driving and damping flux and eliminates the need of a separate damping disk. The only exposed moving parts are a short section of the spindle and a small counterweight. The possibility of bearing troubles is precluded through the mercury flotation of the moving element, which relieves the lower bearing of all pressure and produces a slight upward pressure of only one tenth of an ounce on the upper bearing. Because of the cushioning effect of the mercury, the bearing pivots are prac-

### An Over-Charge of Battery Is Easily Obtained

Adjustments can be made to the meter to provide automatic over-charge of the battery.

tically immune from the effects of heavy shocks and vibration.

The armature box is of molded insulation, specially treated to retard the formation of dross. A non-spilling mercury chamber effectively precludes all possibility of the mercury leaking out, regardless of how the meter is handled.

The adjustment of the meter is very simple, being obtained by means of a single clamp slider which can be securely fastened in position, thus assuring permanent calibration.

A variable resistor element with calibrated scale is provided to give the battery automatically the required over-charge.

### Inductive Time-Limit Motor Starter

To meet the requirements for uniform periods of acceleration of motors, the Cutler-Hammer Manufacturing Co.,

Milwaukee, Wis., has developed the controller shown in the accompanying illustration.

Dashpots and other mechanical and electro-mechanical means of timing the acceleration are not employed, the inductive principle being utilized instead. A transformer is used instead of relays, interlocks, dashpots or other moving parts to control the rate of acceleration. The construction of the controller is simple, and there are no moving parts other than the reversing switches, main magnetic switches and the accelerating switches.

By means of a transformer a holding-out current of transient nature is obtained in successive accelerating switches. Transfer of connections takes place automatically with the cutting out of successive steps of resistance without disconnection of the coil circuits. Adjustments for the timing of the acceleration period of the motor are made on the stationary parts. The acceleration is said to be uniform under ordinary conditions of load variations, the time being somewhat increased on heavy loads.

Particular attention has been given to the ease of replacement of wearing parts, permanency of adjustment, reliability of operation, elimination of ruptured coil circuits and burnouts. Arcing tips are provided and the arc shields of the blowout provide a deep channel in which the arc is disrupted. The main contacts are of the butt type.

### Inexpensive Mine Fan

A new mine fan, designed to handle a maximum volume of air economically, both from the standpoint of original cost and operating expense, has been developed by the American Blower Co., of Detroit, Mich. It is ruggedly constructed in order to withstand general mine usage, and to permit its removal from one location to another without injury.

The assembled fan consists of a disk type wheel surrounded by a steel casing

### Easily Portable Fan

This type fan may be used economically in general mine service. It is ruggedly constructed of steel and cast-iron.

which is fastened to a cast-iron base. This cast-iron base forms the supporting member for two double ball bearings, which in turn carry the shaft on which the wheel is mounted.

So that the wheel may deliver large volumes of air against a resistance, it is provided with twelve overlapping blades securely attached to a large central disk, so as to prevent back flow through the central portion of the fan. These blades are further re-enforced by an annular ring around the periphery of the wheel. The performance is further increased by the use of a steel casing around the wheel to prevent radial discharge of the air. The outfit is arranged conveniently for belting to a motor, or for direct connection, as required.

### Lampless Voltage Tester

A voltage tester which does not require the use of lamps to indicate the voltage has been developed by the Square D Co., of Detroit, Mich. This device differentiates between alternating and direct current, and measures voltages up to 550 volts.

Inclosed in a rugged fiber housing, and of pocket size, the instrument has a broad range of uses, being suitable for locating open circuits, blown fuses and other causes for the irregular op-

### Voltage Tester of Wide Applicability

This device shows the approximate value of either direct- or alternating-current voltages up to 550 volts.

eration of motors. As a voltage tester it is thoroughly accurate, and therefore may be used to roughly check circuits.

### Time-Limit Starter

Each accelerating contactor is controlled through a transformer which induces a holding-out current of transient value. No contractor can close until the current values are satisfactory for the shunting of the starting resistance.

## A Merry Christmas

**T**HIS YEAR *Coal Age* makes Christmas Day the occasion of one of its fifty-two appearances, and we hope that the spirit of Yuletide is still present when this issue reaches you. After all, those men only are happy who carry the Christmas spirit through the year, dispensing cheer, radiating goodwill, turning up the brighter sides of everything and driving away gloom. Americans are happy people. They work hard but they laugh heartily. Joy is in their labor.

The game of life is worth playing. Let us view it as a game to be played well and lustily but without too much resentment if at times the luck seems against us. Its hazards are as necessary to add spice to existence as are the bunkers in a game of golf. Its rains are fruitful as summer showers if rightly used. Some spirits are destroyed and denuded by them, but others are brought only to a fuller maturity. Many a man whose life seems hard, whose labor would appear unusually distressing can smile more and love more and be more than those whose lives are easier, for he has the Christmas spirit not only at Yuletide, when the fires burn brightly, but through the gloomy days, along sodden pathways. Let Christmas guide and cheer us through the New Year to come.

## New Opportunities, New Methods

**I**N THE Connellsville region, coal companies till recently needed only enough coal to charge their ovens, and they could not build many of them for the field adjacent would be worked out before the life of the ovens was fully spent. So there was no anxiety to get out any more from each mine than a certain tonnage and one that has not for years been considered large. But now the coal goes to byproduct ovens and the river affords a cheap way of reaching them, so a new spirit is again in the air and the Connellsville region—the expression is used in a larger sense than is perhaps permissible—is going to see some big changes. The H. C. Frick Coke Co. has quickly recognized that a new day has dawned.

With the broad vision which it always has had, whether under Thomas Lynch or Walter C. Clingerman, it has adopted large methods. The venture at Colonial will be only one of these doubtless. Perhaps we cannot call it a venture; it was so carefully planned, as Thomas W. Dawson shows us in the article which we publish in this issue. Every difficulty was met in advance, every eventuality anticipated. The relative cost of old and new methods was so carefully weighed that there was no venture after all. It was as certain as any business move can possibly be. But it broke so completely with the past that it set the wiseacres gaping.

Now it is done and the system of reasoning back of it explained, it seems so obvious and so clear that we wonder it was not done before. But nevertheless, it is an achievement of a large order. From a conveyor

line a few hundred feet long a jump was taken to one four miles and more in length. The factor of extension is so large that it makes us start. If the H. C. Frick Coke Co. has done this thing, what may it not do in the future?

## We Compliment Mr. Lewis

**I**T MUST be noted that President Lewis of the United Mine Workers is finally trying to put the screws to the recalcitrant anthracite miners in the Pittston region. He has suspended ten local charters, whatever force or effect that action may have, and thereby deals at least a slap, if not a knockout, to several thousand union miners who thought they were superior to international union authority. They struck, they say, because they thought the Pennsylvania Coal Co. and the Hillside Coal & Iron Co. were not making their mines safe enough and then they refused to go back to work pending arbitration, as the international directed. Today they do not belong to the United Mine Workers of America.

This revoking of charters to compel miners to live up to their contracts with operators is commendable on Mr. Lewis' part. Would that the union president had been more vigorous in the past in his defense of labor contract. Had that been his practice, it is possible there would not have been need for it in Pittston now, even though the anthracite union district organizations are chesty by habit and feel themselves almost if not altogether independent of international dictation.

This is the third unauthorized strike of anthracite miners on a large scale during the year. There has been a good deal of previous opportunity, therefore, for Mr. Lewis to crack down on union offenders in hard coal territory. We will not pretend to explain why he did not do so. The union election is over now, however. Mr. Lewis is safely continued in office, and the question of vote-loss does not enter into the matter of punishing miners' locals for breaches of contract.

## Obit Coal Review

**O**UR READERS will be interested to note that the National Coal Association has decided to discontinue its organ the *Coal Review*. Few, if any, publications of industrial and engineering associations have been found self-sustaining. Most of them are a heavy burden upon the body by which they are supported. The National Coal Association has tried out the venture and knows now just what such an emprise promises. At first it had strong hopes of success, but of recent years it allowed the effort to lag and has not supported the paper by large appropriations.

*Coal Review* and *Coal Age* for years have had a friendly rivalry, both papers circulating among a certain section of our readers. Some persons have contended that an association buttressed by the con-

tributions of its membership has no right to enter into the publishing business. Be that as it may, when an association finds that the information it desires to impart to its readers can be more economically transferred to them in some other way, either by communications at stated periods or when occasion suggests, it is not long in deciding that it will adopt some other method of reaching its audience. *Coal Age* will be happy to serve as a medium for this communication.

The officers of the National Coal Association have always, and doubtless will, continue to show the most friendly co-operation with this publication. It promises to continue that service and even to extend it further if that be possible. That is indeed well. The best way to influence the whole industry is by communications to the press of that industry, made, not in an association paper, but as a press release or letter to the editor. Periodicals do not favor copying material from another publication, however authoritative.

Associations are always hampered in issuing a periodical. Everything that appears in it is regarded as official and implicates the association. Consequently the editors cannot have a mind of their own. This makes the copy relatively unimpressive. A pronouncement made by some official body of the organization, it is true, can be published, but any such statement is now regarded as public property and finds its place inevitably into the public press. As a result no matter who may be the editor, he is not able to put into the paper the independence and promptness of judgment that can be shown by the editorial staff of any private publication. An association organ, being a mouthpiece of the whole organization, cannot lead; it must follow. That is why some of them have omitted editorial comment. Others that regarded their duty as being to support higher prices wrote editorials of a kind that could not fail to please the membership but caused suppression of the association.

The way of such an organ is hard. It is regarded, however, as an opportunity to publish at length in all their interminable verbiage, declarations of the Commonwealth and bills in process of consideration. This adds its value to the publication but tends to prevent its being read. Of late the *Coal Review* largely confined itself to Washington news. It frankly converted itself into a gazetteer of Washington and the Association and did not venture into other fields.

### Growing Power of Mine Workers

**I**N VIEW of the fact that the strikes and suspensions of the United Mine Workers of America are among the most painful memories in our industrial history and in the conduct of our home life we must look with regret on the prospect of having the U. S. Labor Department under the control of the President of the United Mine Workers of America, and the American Federation of Labor under that of the secretary of the same organization.

The British public has suffered so severely from the dominance of the coal miners that it would be well for us as a nation to take warning. The Federation of Labor can do as it will. It is not influenced by the fact that the payment of excessive and unusual wages to miners and the inconvenience of long protracted suspensions will be as harmful to its supporters as it is to the other consumers. But surely the Administration will know better than to put the United Mine Workers

in such power that it can control its destiny without any restraint and without any consideration of the needs of the public. Let Mr. Coolidge resist the pressure that is being placed upon him to put the control of the coal industry into the hands of special interests.

Nothing said here, however, should be taken as inimical to William Green, the new President of the American Federation of Labor. He like his predecessor is no advocate of "Rule or ruin."

### What's This? Strike Talk?

**C**OMES now the official miners' union publicity man deposing and stating in print that non-union coal operators and other "union haters" are basely conspiring to produce a general union strike next April. This new discovery—made afresh every now and then ever since the creation of the miners' union—is based on the alleged facts that the non-union operators want to shut off all union coal so that they can gouge the public, while the other "haters" hope a strike will reduce the weakened union to a state of complete collapse.

Could this be an alibi? Are the hard-put leaders of the Mine Workers turning in desperation to their old tactics? Are they hoping they can somehow engineer a strike as the only way out of their difficulties? Let us see.

Here, in an editorial in the official union organ, appears this passage referring to the conspiracy: "President Lewis is cognizant of this situation. The United Mine Workers as an organization is aware of it. The only alternative to a strike is a reduction of wages to the 1917 level." Decipher that.

The union has suffered heavy losses of territory in West Virginia, Kentucky, Oklahoma and in such far-flung regions as Crows Nest Pass in British Columbia. It is suffering severely even in the heart of unionism for lack of work. It cannot stand this strain forever. In view of this situation, do the leaders of unionism feel that the Jacksonville agreement is strangling unionism to death and that wages must be reduced by hook or crook as the only salvation? Then how to reduce them!

Mr. Lewis cannot initiate a move for a reduction. He has taken his stand for "no backward step." If he voluntarily changed that position the rank and file would turn and rend him. The task is to produce a popular demand for a wage cut from that very rank and file before the union disintegrates for want of it.

Why not do it by a maneuver that would cause the union to be "forced into a strike? Miners are notoriously tenacious to the cause of unionism when they are striking for the honor and glory of the organization—certainly more tenacious than in a time of high pay and low work as now. If a strike were to run awhile and the rank and file got ready to accept a wage cut, Mr. Lewis would have been saved the ignominy of proposing the backward step, a dangerous crisis for the United Mine Workers would have been passed and the union, even in defeat, would be stronger than a union choked to death with the Jacksonville agreement.

But it is nearly impossible to conceive of a plausible excuse for striking. Certainly it would be a tough job for the miners' union to justify itself before the public even if it were "forced" into a defensive strike. So we can only remark that if Mr. Lewis feels there is nothing left but battle, his stock of resources is woe-fully low.

Washer of Cia. Combustibles de Agujita.

## Men Well Treated in American Mines of Mexico

Reminiscences of Former Official of Cia. Combustibles de Agujita in Coahuila—Care Taken of Safety, Health and Earnings of Workmen—After Mines Were Destroyed by Outsiders, Company Fed Women and Children

By W. A. ROY

Superintendent, Marine Smokeless Coal Co.,  
Rockwood, Pa.

**D**ESPERATE efforts are being made by the labor party in Mexico to discredit the foreign corporations in that Republic because these companies naturally oppose the policy of confiscation advocated by the leaders of that party, but Ricardo Trevino, who is the Secretary of the Mexican Trade Union Federation, made a bad move, when in his letter to certain members of the British Labor Party he asserted that in the mines of Mexico, which produce chiefly coal and silver, no less than 52 per cent of the men are injured every year by accident. Possibly Mr. Trevino did not expect his letter to be published in the English paper, at least did not expect it to be copied in the United States, where there are hundreds of engineers who know how great an exaggeration such a statement is.

Though not connected with any mining or other interests in Mexico, I have visited nearly every mining field in that country, have friends or acquaintances in many of them and for four years was connected with one of the most important coal operations there. As I speak, read and write Spanish I got my facts first-hand and not from "hearsay." A true statement of these facts is even more to the interest of the Mexican workman than to that of the foreign investors, and as I am at present not connected with either, I feel no partiality and will let no prejudice color my story.

Coahuila is the most important coal-mining state in Mexico. Several big coal companies operate in the Sabinas field about 80 miles from the Texas border.

The Compañía Combustibles de Agujita has coal mines at that place, and, at the time I was there, it was one of the fourteen units operated by the Mexican branch of the American Metal Co., all the other units, except one, being metal mines. The American Smelting and Refining Co. operates the largest coal mines in Mexico, at Rosita, just five miles from Agujita, and an English company operates at Cloete, between Rosita and Agujita. All these companies have mines, coal washers and coke ovens and employ from one to five thousand Mexican workmen.

When I went to Agujita in 1917, it was still in process of rebuilding, after a shutdown of several years, made necessary by the burning and dynamiting during the Carranza revolution. Four coal tipples, a washer, the machine shops, foundry, power house, round house, coke ovens, storehouses, hospital, offices, schoolhouses and residences as well as railroad and mine equipment had to be bought or built. One can easily see that it was no light investment for the operators.

### PICKED UP STRENGTH AFTER PERIOD OF WORK

It was pitiful to see the half-starved haggard men who, in ever increasing numbers, flocked in hoping for an opportunity to work. More than we could use came, bringing their families and all their worldly possessions, sometimes packed in the high two-wheeled Mexican carts, drawn by thin patient little "burros," sometimes in a ragged bundle on their shoulders.

At first it took four men to do the work that one good husky American could have accomplished, but it was remarkable that they could work at all, considering that most of them had been living on the "husks of nothing" for about three years and, after they had been with us a month or two, it was hard to believe that they were the same men.

After the four mines were opened and the washer and coke ovens in operation, we employed over two thousand men and though there were, of course, many minor accidents, the company, through self interest, if nothing else, used every means to make them as few as possible. Each man received compensation from the company the entire time he was disabled and for the small stipend of 60 centavos a month he got medical attention and medicine, not only for himself but for his entire family. The doctor in a mining village is usually absolute monarch in his department, and at Agujita he had a druggist and a trained nurse to assist him.

He had also a sanitary corps consisting of twenty

the general manager made frequent inspections, and we all believed that "constant vigilance is the price" of safety. One of our mines was very gaseous and unfortunately the Mexican miner adores his cigarette, but though there were 800 men employed in this gaseous mine, only three fatal accidents occurred in this particular mine during the four years I was with the company and only one fatal accident in all the others. This is not guesswork, but a matter of actual record, kept both by the mining company and by the Mexican civil authorities of that district.

Knowing the miners' tendency to gamble with his life we had safety lamps of the most improved type which were kept in a lamphouse near the head of the shaft under charge of competent and trustworthy men. Each miner received his locked and lighted lamp as he went to work and returned it as he came up the shaft. He was not only required to turn over to the man at the lamphouse any matches or smoking material he might have in his possession, but he was searched to see that he was not hiding any from us, both before

#### Patio and Shops

At Almacén No. 2 mine, Agujita, Coahuila, Mex. The patio is the fenced area in which the town is located. The company removed garbage, oiled water holes and kept the village in sanitary condition. The area occupied by the village merchants outside the patio and the jurisdiction of the company showed neglect.

men whose duty it was to keep the streets clean, to dispose of garbage, to oil water holes and to do any other work the doctor considered necessary for the health of the village. The company employees lived in a part of the town separated from the Puestos—as we called the quarters occupied by Mexican tradesmen—by a small park and a fence, but the cleanliness on one side and the filth on the other made a more striking division.

#### NEVER KNEW MINES WITH FEWER ACCIDENTS

I have been a mine superintendent for twenty years, but I have never known any mines where there were fewer accidents than at Agujita. It was not because the mines are inherently safe nor because the Mexicans are naturally careful. Quite the contrary: but we rigidly required compliance with every safety rule in force in the mines of the United States and added some extra ones made necessary by local conditions, and took every precaution humanly possible to prevent accidents or injury. And here I want to pay tribute to my Mexican mine foremen and firebosses. They had no certificates, I trained them myself, and though they probably would have flunked on any written examination, they were as trustworthy and efficient as any men I have ever had to work with me.

All the Agujita mines were well ventilated and kept clean, and one foreman stayed in each mine eight hours every day, the superintendent visited every mine daily,

entering the cage and after he got out at the foot of the shaft. As one man was discovered to be smuggling cigarettes and matches in his hair you can see that the search needs to be thorough.

#### RAISED WAGES BUT GOT LESS COAL AS RESULT

The Mexican makes a good miner, but he is not what you would call an enthusiastic worker and with few exceptions if he meets his daily needs he takes absolutely no thought of the morrow. To get results one must know his peculiarities and shortcomings and how to sidestep them. For instance we decided at Agujita that we could afford to give our miners a wage increase if it would produce a larger tonnage, and we were chagrined and surprised to discover that the wage increase had just the opposite effect from what we desired and expected.

On investigation we discovered that from the time the wage increase went into effect most of our best miners had acquired the habit of taking from one to three holidays a week. They were making enough for their actual needs on the old schedule and so higher pay only meant more leisure for them and we had to work a new scheme on them. We revoked the wage increase and gave them a tonnage bonus which amounted to the same thing, only if a man did not work regularly and get out the tonnage that the foreman and I decided was reasonable he got no bonus. The scheme worked beautifully, and we doubled our

output, but perhaps Mr. Trevino would consider this cruel and barbarous treatment.

Care to prevent accidents may be due to self interest but, self interest does not dictate all that the companies in Mexico do for the welfare of the people; nearly all mining villages and all of those belonging to the large companies, have recreation buildings and equipment, schools, medical attention and supervision, and all the officials of the company are instructed to, and do, take a personal interest in the welfare of the people in the village.

#### INFLUENZA WORKS HAVOC EVERYWHERE

In the big "flu" epidemic of 1918 our whole camp was stricken as with a plague. I have had to help men up out of the mine and have them carried home, who went to work in the morning apparently in perfect health. Hundreds of our workmen and their families were stricken at one time. We had orders from our company to feed at the company's expense all families where the wage earners were ill, to give them all the medical attention they needed, to furnish coffins and to bury free all the dead and to do everything possible for the living. Of course money could not buy adequate medical attention. No extra doctors were available, for the plague raged everywhere, but our doctor ate and slept (if he slept at all) on the move, and every mine official, who was not himself ill, devoted all the time his work left him, to helping the doctor in his work. The fatalities were enormous, for the Mexican seems to lack stamina to resist disease. However, compared with that in the native towns, under native management, our mortality rate was almost negligible and fortunately the plague was not of long duration.

From 1918 to 1920, Agujita, barring a few bandit raids and excitements, was a peaceful, prosperous little mining town where work was plentiful and well paid, the people busy and contented, with the exception of a few malcontents who could be satisfied only by what Harry Lauder defines as a labor government, "All play, no work and all pay," when almost over night a crowd of agitators, from God knows where, invaded our camp, gathered in our malcontents and organized a sort of a local Soviet. How failing to get our men out by

oratory they resolved to use force, seized the power plant, and forced the men out of the mines by shutting off the ventilation, how they made "Muere los gringos" (Death to the foreigners) their slogan, and after asking impossible concessions of the company and being refused, they with de la Huerta's connivance, seized the mines and made a glorious fiasco of operating them, is too long a story to put down here, but that even under these circumstances the "Gringo" organization was not indifferent to the welfare of the people is proven by the following letter sent out from company headquarters:

#### FEED FAMILIES OF MEN WHO SEIZED MINES

Compania de Combustibles Agujita

Sabinas, Coahuila.

Gentlemen:

We acknowledge receipt of your letter of Oct. 16, and from copies of letters written to Mexico City, we think you will see our point of view, with regard to what we wish to be done at your camp.

In view of the fact that the mines have been flooded, pumps drowned and fans have stopped you can now assure any of the men with whom you talk, that we are not in any hurry whatsoever to start up the properties and that as long as the agitators who have brought all this trouble continue in this district, we would just as soon remain idle. We feel sure that the trouble has all originated with the agitators who have come into your camp and that it will pass with them and that they have willfully and maliciously deceived the miners and other men who work for you and that they must be defeated.

Referring to last paragraph of your letter, we wish to say that we do not bear any malice to any of the men, except the agitators and we do not wish to see the women and children suffer from hunger. We desire that you make every effort to locate any that are actually in need and see that these women and children are fed. We do not wish to feed any idle men, but we think that you can arrange to have some of the Mexican women in the camp work for you making tortillas and soup and cooking beans, and you can let it be known that any women and children who are hungry will receive one good meal a day at the company's expense.

Please advise if you can fix up this free kitchen and service and make every effort to help those who are in need of help.

COMPANIA MINERA DE PENOLES.

I have written only of the companies for which I worked but almost everything I have said of this company is true of all companies formed by foreign capital in Mexico. The real workmen know they are better treated and better paid, under foreign than under native management, but unfortunately it is never the real workman who gets his views into print.

Manager's residence on right, a low ranging building with good ventilation and high rooms.

## Matanuska Coal Field Mines Only 7,000 Tons Monthly

Coal Varies from Lignite to Anthracite—Latter Is In Places 40 Ft. Thick but Folded and Penetrated by Dikes and Sills

**D**ESPITE all that has been said of the fortunes in coal that might be made out of the Alaska coal fields, the Bering field is still undeveloped and the Matanuska field is only producing 7,000 tons a month, less than two or three shafts in the United States can and have hoisted in a single day. What follows regarding the latter field is published on the authority of the U. S. Geological Survey.

The Matanuska coal field, which contains one of the most valuable coal reserves in Alaska, extends from an area near tidewater at the head of Knik Arm, an inland extension of Cook Inlet, eastward to the upper valley of Matanuska River, reaching a point within 8 miles of Matanuska Glacier. The Matanuska branch of the new Government railroad taps this coal field and draws from it much of the fuel used on that railroad.

Although the coal-bearing formation is of the same age throughout the field the coal shows a wide range in character. At the west end of the field, where the beds are only a little deformed, the coal is a lignite. Farther east, at Moose and Eska creeks, where the beds are somewhat folded and faulted, they contain bituminous coal of good grade, which is now being profitably mined to an extent justified by the market demand. Here several mines are now producing about 7,000 tons a month. Still farther east, in the vicinity of Chickaloon, the terminus of the Matanuska branch of the railroad, the coal is a bituminous coking coal of the first rank, but the structure of the beds is more complex than at Moose Creek. The coals of the highest grade, which are found on Anthracite Ridge, 12 miles east of Chickaloon, include anthracite of superior quality, but the beds are highly complex in structure. No attempt has yet been made to mine this anthracite.

### SURVEY RECENTLY COMPLETED

The part of the Matanuska Valley that includes the area near Chickaloon and the area immediately east of it form what is generally known as the upper Matanuska Valley. A survey of the upper Matanuska Valley, an area which is about 10 miles wide and extends 18 miles eastward from Chickaloon, was completed in 1924 by S. R. Capps of the Geological Survey, Department of the Interior, whose work supplemented a survey of a part of this area made in 1913 by G. C. Martin and associates. The lower part of the Matanuska coal field has already been surveyed. A report showing the results of the work done in 1924 is now in preparation.

No mines are now regularly operated in the upper Matanuska Valley. Mines opened from 1920 to 1922 by the Alaska Coal Commission at Chickaloon and on Coal Creek produced coal of high grade, but the beds were so much broken up or altered by faults and bodies of intrusive rock as to make the cost of mining very high, so that the work was stopped. Development work at a mine on the west bank of Coal Creek, however, is being continued by a private company.

The field work of 1924 indicates that the coal-bearing area east of Chickaloon is somewhat smaller than had been supposed. The dominant structure of the basis

is synclinal, and considerable areas of it that lie south of the axis of the syncline are now thought to be stratigraphically below the coal-bearing horizons at Chickaloon and to contain no workable coal. The coal beds at Coal Creek and at O'Brien Creek are believed to lie in faulted synclinal folds, most of the coal having been removed from the corresponding anticlinal folds by erosion. The reserves of minable coal at each of these places are believed to be limited to a few hundred thousand tons.

The coal-bearing area on the south flank of Anthracite Ridge contains beds carrying anthracite coal of excellent grade, which is exposed at many places. At a place on the head of West Fork of Purington Creek a bed of anthracite nearly 40 ft. thick crops out. In this area, however, the coal-bearing formation is highly disturbed by folding, crumpling, and faulting, as well as by bodies of intrusive rock, such as dikes and sills. The coal beds appear to lie in synclinal basins, most of the upper part of the folds having been removed by erosion. These beds no doubt contain considerable excellent anthracite coal, but whether it occurs in beds sufficiently large and continuous to justify the expense of mining is uncertain in view of the cost of building a railroad to it. Little prospecting has been done on the anthracite beds, and whether they include workable bodies of coal can be proved only by extensive exploration, both on the surface and underground.

### WILL NOT PAY COST OF BETTER COAL

The beds of bituminous coal near Chickaloon are so complex in structure that the coal cannot be mined for general use in steam raising in competition with the more cheaply mined coals of the lower Matanuska Valley, where, though the coals are of lower grade, the structure is simpler. The utilization of the coals of the upper Matanuska Valley depends on the development of a market for superior coals that cannot be supplied from the other beds in this region, on a price sufficient to yield a profit, notwithstanding the comparatively high cost of mining them, and on their ability to compete with coals of similar grade mined in other fields. The high-grade blacksmith coal of the Chickaloon area and the anthracite must compete with coal mined in the eastern part of the United States, but the cheapness of transportation of the high-grade Matanuska coals to markets on the west coast of the United States should favor their development. It is also possible that the market for the somewhat lower grade bituminous coals now being mined in the Moose Creek and Eska Creek districts could be extended to supply a demand now met by similar coal mined on Vancouver Island.

### Headframe at Rachel Mine

One of three shafts at this mine, all 360 ft. deep. The coal is hoisted by electricity. Coal is screened into 4-in., 2-in., ¾-in. and slack.

## Four-Mile Belt Line Carries 9,426 Tons of Coal In One Day at Frick Company Mine

Nineteen 48-In. Belts and One of 60-In. Deliver to River Dump All Coal from Three Mines Formerly Entered by Shaft—Thirty-Five Cars Discharged at One Time by Each of Two Revolving Dumps

BY THOMAS W. DAWSON  
Chief Engineer, H. C. Frick Coke Co.,  
Scottdale, Pa.

IN 1916 the H. C. Frick Coke Co. completed the arrangements necessary to load all coal from its mines lying directly along the Monongahela River in barges for transportation by water to the Clairton byproduct ovens. The plans of the U. S. Steel Corporation called for a further extension of its Clairton plant, which would require about 50,000 more tons of coal weekly than could be furnished by the river mines already equipped. Hence, it was decided to develop other coal for river transportation. This necessitated taking coal lying farther back from the river than was usually thus transported.

Colonial Mines Nos. 1, 3 and 4, of the H. C. Frick Coke Co. could be reached through the Alice Mine, of the Pittsburgh Coal Co., which was being operated as a river mine. These latter workings were almost exhausted and their main headings reached to the boundary of the Colonial coal field. A careful examination of the mine was made, and it was purchased from the Pittsburgh Coal Co. as an outlet to the Monongahela River for the three Colonial mines to which a large field of coal had been allotted. Probably the best way

in which to define its size is to say that it will have a life of twenty-five years when worked at the rate of 8,500 tons per day for 300 days in the year. After the purchase of this mine no further work was done until the Spring of 1918.

The problem facing the H. C. Frick Co. was the mining, transporting and loading in barges of 8,500 tons of coal per day, of which Colonial Nos. 1 and 3 were to produce 3,000 tons each and Colonial No. 4, 2,500 tons per day. Each of these mines was producing coal for the manufacture of coke in beehive ovens, having a total daily production of 3,350 tons for the three plants. This made it necessary to furnish each of these mines with sufficient equipment and also with the housing facilities for the additional men that must be employed if the needed tonnage was to be obtained from this field.

The coal being produced at this time was being hauled away from the river in most cases to the three shafts where it was hoisted and coked, and the coke shipped by rail to the steel plants. This arrangement made it possible to keep up operation without interference until the new scheme was completed, when the haulage was simply reversed and the coal taken to the river making the equipping of the mines a simple matter. They had to be supplied only with additional power,

NOTE—Article entitled "Underground Belt Transportation of Coal," read before the Coal Mining Institute of America, at its Pittsburgh meeting, Dec. 4.

mine wagons, mining machines and new haulage roads leading toward the river.

On the surface, a new town was built at each of the mines to accommodate the additional men required in the production of the larger tonnage. Attractive houses were built and the towns well laid out with graded streets, shade trees and sidewalks. A filtration plant was built to furnish both the old and new towns with filtered water, which was piped into the houses. Many of these dwellings have bathrooms and all are equipped with electric lights. A large boarding-house and bath-house were built at each town and all possible care taken to provide for the comfort and convenience of the men employed.

The improving and equipping of these three mines to produce the required tonnage was a comparatively simple matter, but the transportation of this output from the working face to the river was a problem which required careful consideration.

Naturally the first scheme considered was the transportation of this coal by electric locomotives and this method would undoubtedly have been adopted had not more than ordinary difficulty been encountered in providing adequate haulage roads.

#### HAULAGE TRACKS WOULD BE INADEQUATE

When Alice mine was purchased from the Pittsburgh Coal Co. it was almost completely mined out. Two headings remained from the boundary of the Colonial field to the river, but little pillar coal was left to support the roof. In fact, in several places the pillar on the outside of the headings had been pierced by room work, and holes had been stopped with burlap sacks in order to maintain proper ventilation. It was not possible to provide more than two tracks from the Colonial mines to the river. One of these must accommodate loaded, and one empty trips. Extensive roof protection was necessary in both of these headings to protect such important haulage-ways as these would have to be.

The mouth of this mine is just beneath the tracks of the Pittsburgh & Lake Erie R.R., and only a few feet above high water level of the river. The entire bank between the railroad tracks and the river, where the outside landing and river tippie had to be located, moves toward the river every year, necessitating extensive foundation work for the large trestle and tippie which would be required to handle this tonnage. The wagons in use at these mines had an average capacity of about 2.1 tons each, and, to produce 8,500 tons per day, would require handling about 4,000 of these wagons, or forty trips of one hundred wagons each. This would allow only 12 min. between trips regularly throughout an entire eight-hour day.

The H. C. Frick Coke Co. has had some experience with derailments, and this looked like a large undertaking. It was decided to abandon this small wagon, and one was adopted, for estimating purposes, of 3½ tons capacity, reducing the number to be handled to about 2,400, or twenty-four trips of one hundred wagons each, which, on such grades as must be traversed, require the use of a 75-ton locomotive to handle the load. An estimate of the cost of completely equipping these mines on this basis was prepared, but, due to the necessarily expensive outside arrangement and the danger anticipated from the sliding of the river bank, the scheme appeared unsatisfactory.

Four of the H. C. Frick Coke Co.'s mines were delivering their entire output on the river, all of which was

carried on belt conveyors from the shaft to the river, an average distance of about 500 ft. These were operating very satisfactorily, no delays being experienced in the operation of these installations. This led the staff of the H. C. Frick Coke Co. to conceive the idea of making the terminal of the locomotive haulage inside the mine where sufficient trackage could be obtained, transporting the coal outside to a much simplified tippie on the river. This would eliminate most of the danger from slides, decrease the length of locomotive haulage and materially lessen the cost of the loading arrangement at the river.

Further study along these lines indicated that, in order to get a satisfactory inside terminal for the locomotive haulage, the mine conditions would make it necessary to go back so far as to require an extensive system of belt conveyors. A careful analysis of the cost of operation of the various belt conveyors already in use gave conclusive evidence that these units could be installed in considerable number and operated at a saving over the original scheme involving locomotive haulage. This led the company to look into what then appeared a rather daring scheme.

As already stated, the size of the mine wagons would have had to be increased if the scheme of locomotive haulage had been adopted. The mines had 996 mine wagons already in service, most of which were in good operating condition. By taking the belt-conveying system back to a point or points where it could be reached by the existing equipment, the tonnage could be produced simply by purchasing a comparatively small quantity of new equipment for these mines and utilizing everything already in service. Two points in the field were selected. At one of these the Colonial No. 4 was to discharge its output. The other was for the discharge of coal from Colonial Nos. 1 and 3. Landings were planned separately for each mine so that each could operate as a separate unit with no interference from the other and with none of the mines using common tracks. This would allow the management to hold each mine responsible for its tonnage in exactly the same manner as if it had been delivering to its own shaft bottom, as it had in the past.

#### FIRST SCHEME PROPOSED TWO-CAR DUMP

A double landing was proposed for Colonial Nos. 1 and 3, each side having its own two-car rotary dump with both dumps discharging through a common hopper to an apron feeder designed to feed 860 tons per hour to a belt conveyor of the same capacity. Colonial No. 4 was to have a landing with a dumping arrangement of the same kind, served by a branch belt fed by an apron conveyor at the rate of 360 tons per hour. The conveyors from Colonial Nos. 1 and 3 were to be 42 in. wide, and from Colonial No. 4, 36 in. wide to their junction, from which point all remaining conveyors were to be 48 in. wide and carry 1,220 tons per hour. This rating would allow the proposed output to be handled from these mines in seven hours' working time, allowing one hour for unavoidable delays.

A detailed estimate was made along these lines for comparison with the one already made on a locomotive-haulage system, and it was found that the initial cost of the belt-conveying system would be less than the locomotive haulage system and would effect a slight saving in operation. These estimates were carefully checked several times during the next year, and the management was finally convinced that the belt-convey-

ing system was the correct plan for this project. Sufficient money was appropriated to cover the cost of the entire project, including new towns, water system, new electric power system, additional mine equipment and the conveying system, and the work actually started in October, 1920.

Specifications were immediately issued and bids on equipment asked from all the manufacturers of conveying equipment in the country. The designing at the start was naturally required to proceed with the work in the field, on account of the many limitations encountered which would not exist in outdoor work. All water entering the headings must be drained away and pumped outside. This makes it necessary to fix the grades on the conveyor to correspond with the drainage grades as nearly as possible. Ventilation must be taken into account. Grades must be established that will make it unnecessary to disturb either roof or bottom and adequate roof protection must be provided at all points.

It became obvious early in the development of this scheme that it would not be advisable to drive any of

give a clear discharge of the coal from belt to belt. This made a careful design of chutes between conveyors necessary and also made it obligatory to locate the drives back of the head pulley where they could be kept close to the floor. Throughout the part of the system located in the old Alice Mine headings these drives were all located in break-throughs where little additional solid coal had to be removed. In all cases the drives were kept as close to the head end of the conveyor as local conditions would permit.

At the very start of the design of this conveying system it was evident that it required little ingenuity to put together a series of belt conveyors to carry coal at the specified rate for this distance, but that the designing of such a system, keeping the cost, maintenance, power and attendance down to a point where it would be a truly economical system, was a real problem. In solving it the view was taken that the power for driving a conveyor is the most important consideration. The actual power consumption, though a considerable item in the operating cost, is the smallest measure of its importance in the design. The power required

#### Tandem Drive with Take-Up

Near the end of Belt No. 2 at the entrance to the Colonial Mine. Note the track which nearly all the way follows the conveyor line and is used for the lubrication car and as a supply track for the maintenance of the conveyor. As the old Alice Mine had a double track there is plenty of room for this track and the belt, side by side. Note also the cross beams. Throughout the Alice Mine passageway, steel work or brick arches have had to be provided.

these conveyors at the head pulleys, as is ordinarily done. The roof in this mine will stay up fairly well if the checker slate above the coal is not broken, but as soon as this is fractured high falls are almost certain to occur. This condition, if for no other reason, made it necessary to keep the height at which one belt discharged to the next one in the system as low as possible.

It was made clear in the comparison of operating costs of the two schemes that one of the main factors operating against the belt-conveyor system was the power required for its operation. It was apparent that a large part of this excess power was required to lift the coal the extra height at each belt intersection that would enable it to deliver the coal to the next unit. Where twenty units were required, the lifting of 8,500 tons of coal per day a matter of only a few inches at each intersection would show on the annual power bill.

These two considerations made it essential to keep the height between the tail pulley on one conveyor and the head pulley on the next to the minimum that would

fixes the size of motor and control, the size of the main shafts and the gear reduction and the ply of the belt, all of which directly affect the installation and overhead costs and, just as surely, the maintenance and replacement costs.

As a first step a series of power tests was run on the four conveyors already operating along the Monongahela River, and a formula was developed which would as nearly as possible fit all when length, speed, load and lift were taken into consideration. Knowing the conditions under which these conveyors were operating, this was considered a good basis from which to start in designing conveyors of a much greater efficiency. With this data lengths of conveyors were established with which it was certain the belts could be driven successfully. The data shown in Table I were compiled and from these the entire system was developed step by step.

It was believed that the first consideration in power reduction was the development of a better carrier than

had yet been placed on the market. The engineers started systematically "talking carriers" with all manufacturers and got as many as possible interested in making improvements which would meet the needs of the installation. The first requirement specified was that all bearings should be of high-grade anti-friction type with either ball or roller bearings. Lubrication must be positive and a system adopted which would make every bearing easily accessible for the future application of lubricant and reduce to a minimum the labor involved in taking care of the lubrication.

In this system there are in service 6,598 carriers, which makes the attendance to bearings and their proper lubrication important. To get the highest possible efficiency from these carriers every bearing must be in perfect condition, and, in order to keep them so, they must always be lubricated thoroughly. This brought up the question as to the number of pulleys to the carrier and a consideration of the three-pulley type was started at once, in order to reduce the number of bearings and, consequently, the amount of attendance necessary. The question of belt wear necessarily had to be considered when entertaining the idea of a change from the five-pulley type which has become practically standard. This was given much consideration and a meeting finally was held with several of the foremost manufacturers in which this feature was discussed for almost an entire day in open meeting. As a result of this study, the three-pulley type was adopted. This reduced the number of bearings, and, consequently, the number of places to be lubricated, from 65,980 to 39,588, a reduction of vital importance. With the three-pulley carrier adopted, the trough of the belt is practically the same as with the five-pulley type. It appeared certain that the carrying capacity of the belt would not be reduced materially.

#### BIDDERS FURNISH MODELS

Each manufacturer submitting a bid was required to furnish a sample carrier of the type proposed in his proposition. When all these were received and set up in one room, an excellent collection was available from which to choose, and they were carefully examined before a final selection was made. It became apparent, soon after bids were examined, that to get what was wanted for this system it would be necessary to consider each item of the equipment separately and purchase each major part of the equipment from the manufacturer giving the best in its line.

The carriers were purchased from the Stephens-Adamson Mfg. Co. This is a three-pulley carrier equipped with No. 204 S. R. B. annular ball bearings. It is substantially made, and all castings are of malleable iron. The bearing housings are of malleable iron, designed with a liberal grease reservoir and mounted so as to oscillate and thus take care of any inaccuracies in alignment—either in manufacture or due to accidents to the equipment. It has one unique feature which has proven very useful in operation. The entire upper part of the carrier pivots on a fixed shaft, allowing it to be turned back under the belt and laid down on the decking, thus permitting each unit to be examined and repaired, if necessary, while the belt is in operation. The return carriers are made of 7-in. tubing with a through live axle and supported at each end on the same bearings in the same mountings as used in the troughing carriers.

After selecting the carriers it was decided that none

of the drives submitted in the original proposals from the manufacturers were satisfactory, and another drive was designed in the company's office which would answer the purpose, new bids being obtained based on this design.

The motors, which were purchased from the General Electric Co., are of the wound-rotor type, 2,300-volt, 3-phase, 60-cycle, 900 r.p.m., the driving pulleys being required to make 40 r.p.m. The motors were to be set in separate drive rooms located back in the coal, and it was very desirable to take all gears out of the main gallery in order to conserve space and remove all possible hazards in operation. A double reduction gear box was designed as a unit to be installed in the motor room between the motor and the tandem driving pulleys. These pulleys were connected to the gear-reduction unit by two extension shafts fitted at each end with flexible couplings of the rubber-bushed pin type to allow for errors in alignment. Cut-steel herringbone gears of small diameter and wide face were used, and all shafts were mounted on high-duty Hyatt bearings.

This construction was adopted in order to get the highest possible efficiency from the drives and to allow

**Rotary Dump Discharges 35- to 40-Car Trip**

Not an impressive illustration, but the dump is 374 ft. long and has a hopper beneath it holding 1,250 tons and thirty-four duplicate feeders which deliver coal to the belt as it is needed, preventing the overloading of the conveyor and providing, to a large extent, against underloads. Without such a stabilizer as this hopper and feeders the belt would travel empty quite a proportion of the day.

the entire unit to be made accurately at the factory, assembled, tested and shipped complete inside the gear box ready for erection in its room. All gears run in oil, and the roller bearings are equipped so as to be readily accessible for lubrication. The connections between the gear boxes and the motors are made with Falk-Bibby couplings. Seventeen duplicate units of this kind and three of similar construction, but for single drives, were used in this installation. This equipment was purchased from the Falk Corporation.

All drive and head pulleys are of 48 in. diameter, cast-iron, with split hubs mounted on 7½-in. diameter shafts. These shafts are carried by two 6x7-in. heavy duty Hyatt bearings in specially designed ball-and-socket housings. Heavy cast-iron bases are used to mount these bearings. In the erection these bases were accurately set to alignment and level, with no provision for adjustment. This worked out nicely, saving time and giving perfect satisfaction. All snub and tail pulleys are of 36-in. diameter, with 5½-in. diameter shafts, equipped with 5x4-in. heavy-duty bearings mounted in the same way as the larger ones.

The driving pulleys are lagged with 4-ply rubber belt. On the tandem drives the belt is laced underneath first, thus putting the clean side of the belt against the main driving pulley. Each drive has a take-up pulley weighted to apply about 2,000 lb. initial tension to the belt. Just ahead of each take-up pulley is a snub pulley which is provided with a solenoid brake to stop the conveyor and hold it in case there is sufficient lift to cause it to run backwards after the power is shut off. The Stephens-Adamson Mfg. Co. supplied this equipment.

After this type of equipment was selected a complete conveying system was obtained on which every bearing was either of the ball or roller type and the lubrication taken care of as carefully as possible throughout the entire system. The large roller bearings required in the drives added considerably to the expense of the installation. By this refinement an actual saving in the installation cost was expected, and basing the figures on this class of equipment the figures shown in Table II were prepared which, when compared with those in Table I, show that it was possible to reduce the ply of the belt required from a ten-ply in a large part of the system to a uniform eight-ply throughout the entire system. This reduced the cost of the belt on the entire installation about \$50,000, paid for the bearings and more than justified expectations in regard to reduction in power, as will be shown later.

To provide for lubrication, every bearing in the system was equipped with an Alemite fitting. A special grease car has been built carrying a barrel of grease and a compressor for forcing it through a flexible tube which reaches all the bearings. By the use of this car all equipment can be lubricated at any time. This allows fixed periods to be set between complete lubrications of the equipment. Everything is so arranged throughout the system that every bearing can be lubricated with a standard grease gun while the conveyors are running, if this should ever be necessary.

After taking care to reduce friction to a minimum in all the mechanical equipment, the fact that friction just as serious may be developed within the load carried was not disregarded. In case the belt is flattened out at any place the load loses its form and must be forced back to its original shape in going through the next carrier. This requires power and may readily

\* Stress in lb. per in. of width per ply.

become a source of increased power consumption. In order to avoid this, the load must be carried along in a perfectly quiet state with absolutely no changes in its physical form. To accomplish this, all changes in grade over vertical curves were made of as long radius as possible, using troughing carriers throughout the entire top run. Carrier spacing was fixed at an average of 3 ft. 6 in. with graduated spacing from the head to the tail end. Various other spaces were tried on a few conveyors, but no accurate data have yet been obtained. In the erection of carriers, marks were set on the steel stringers on each side at right angles to the center line of the belt to insure accurate spacing and alignment of carriers. All carriers were clamped to the steel stringers in order to allow of readily changing the spacing.

The belt for this system is 8-ply, 32-oz. duck,  $\frac{1}{8}$ -in. rubber-covered, with the exception of one of the shuttle conveyors, the 60-in. feeding belt, No. 20, under the dumping hopper and belt No. 19, which are fabric belts manufactured by the Imperial Belting Co. The other belts are divided nearly equally between the Goodrich and Goodyear rubber companies.

It was recognized that, on a system as extensive as

this, mechanical belt splices would be a serious handicap, and so the question of vulcanizing them in the field was discussed with the belt manufacturers. Three of these units required over 3,000 lin.ft. of belt and the average was about 2,000 lin.ft. Due to limited headroom in the belt gallery a roll of belt more than 700 ft. long could not be handled, and most of them were nearer 500 ft. long. The entire system required a little over 47,000 ft. of belt, making over 100 splices in the entire system. A portable electric vulcanizer was developed by the Goodyear Tire & Rubber Co. for this job. The vulcanizer was purchased and contracts made with both the Goodyear and Goodrich rubber companies to make vulcanized field splices on their own belts with this equipment, leaving only one mechanical splice in each belt which it was purposed to vulcanize later after the belts had stretched.

This is one point where the calculations went astray.

#### Belt at Colonial Mine

All the belts are 48-in. wide except No. 20 which is 60 in. wide. It will be noted how the carriers are supported, so that they can be turned over on the decking while the belt is running and can be cleaned or repaired. It is remarkable how certainly the coal stays on the belt. Not a lump rolls to the floor. Its motion along the road is one of translation only. The belts carry 1,500 tons per hour at a speed of 500 ft. per minute.

Over one million tons of coal have been carried on these belts and none of them have stretched over 2 or 3 ft., which does not allow enough belt to make a vulcanized splice. In this time of operation the original mechanical splices have had to be cut out on each belt and renewed once. The vulcanizing is well justified, and preparations are now being made to vulcanize all these splices by the addition of a short piece of new belt and a double splice. In making these splices originally the ends of the belts were stepped down in the factory and vulcanized after the belts were placed on the carriers. This was a successful undertaking and has eliminated much trouble in operation.

The first power analyses, as shown by Table I, disclosed the fact that, with instantaneous starting, the power to start would be about three times that of running. As the conveyors used for these determinations were driven by direct-current motors, tests were made of delayed starts by making contacts through a barrel of water and timing the start while measuring the power. From these data it was decided to specify as long a starting duty as possible on the controls to the motors. This was worked out so as to get a 15-sec. starting duty, which reduced the starting power to about twice that for running the loaded belt. This not only aided in keeping down peaks on the power demand, but materially reduced stresses on the equipment.

The electrical control for a system of belts of this

kind required careful consideration. They must be necessarily interlocked to operate as a unit, and a certain amount of flexibility must be maintained. The control is located in the No. 1 drive room at the river. An operator is stationed at that point to control the entire system and take calls from the various patrolmen. All units are connected with this room and the office by telephone, and instructions can be issued by telephone from either the office or control room to any drive room as needed. The operator can start or stop the entire system by simply pressing a button in this room.

On one panel of the board is mounted a voltmeter which indicates at all times which belts are running and allows the operator to know at a glance where trouble is located, if any should occur to stop a conveyor. The control panels are interlocked so that by cutting out resistance at each motor room as the last accelerating contactor goes in, the reading on the volt-

meter is increased to show the conveyor in operation. When conveyors are stopped, this process is reversed.

When the belts are loaded from the dump to the river and a start is to be made, the operator simply presses the main control button and conveyor No. 1 starts, and as soon as it reaches full speed, or in about 15 sec., No. 2 automatically starts, attains full speed, and No. 3 starts, all conveyors continuing to start in the same manner until the entire system is operating. This manner of starting prevents building up a peak load, allowing the entire system to be started without any excess over the regular running load, with the exception of the extra starting load on the last conveyor.

The equipment is so interlocked that if any motor is shut down at any place in the system, every conveyor back of it is automatically stopped instantly. This stop may be caused automatically by a line contactor of any starter opening due to overload, by the breaking of a conveyor belt, or by a belt slipping on one of the driving units more than a predetermined amount. In case of power failure, all motors will stop and will not start again upon return of voltage, but the system must again be started from the main control room.

Each conveyor is provided with a limit switch operated from the idler pulley of the belt takeup, so that if the belt stretches beyond a certain point or breaks, the motor will be shut down and all motors back of it will be shut down at the same time. An emergency

switch is located in the belt gallery near each motor room, which, if opened automatically, stops all motors. All these switches must be closed before the accelerating equipment will be operative. Each starting panel is provided with a switch by which it may be disconnected from the master control system and operated as a unit if required in case of testing, splicing a belt or any other cause requiring such operation.

In making a stop these belts will naturally coast varying distances due to the difference in lengths and lifts, and while solenoid brakes are provided on each conveyor, it was not considered advisable to set them so that they would engage hard enough to bring the belts to an immediate stop. To prevent a free-running conveyor from discharging coal upon one ahead which had stopped, a mechanical interlock was installed between the head and tail pulleys of each conveyor on the system. This engages whenever the conveyor at the rear tends to run faster than the one ahead of it and prevents any piling up of coal in the chutes. As all these safeguards are working satisfactorily, we have never had any trouble with these conveyors.

#### CHUTES LOAD UNIFORMLY

The designing of the chutes between conveyors gave much trouble as the headroom has to be kept to a minimum. The large lumps sometimes clogged the chutes a little as originally designed but this was easily corrected by cutting a V-shaped notch at the bottom. The chutes now load the conveyors uniformly throughout the entire system.

It required better than ordinary provisions to transfer this large coal tonnage from mine wagons to the conveying system. With the mine car in use, over 4,000 cars have to be dumped daily. The original scheme contemplated dumping two cars at a time with three dumps. This required large landings for empty and loaded cars and a large number of men for handling cars and dumps.

Consideration of this scheme developed a plan of consolidating this work all at one point and dumping entire trips of thirty-five cars each in a revolving dump. This scheme reduced the track for landings 18,000 lin.ft., the number of mine cars by 238, and the number of men required by eight. This scheme was adopted and the landing laid out with two 35-car rotary dumps, each 374 ft. long, set over a bin of the same length with a capacity of 1,250 tons. This gives a storage of one hour between the mine and the conveying system without tying up mine cars.

In the case of each mine, when a motorman arrives at the dump landing with a loaded trip, he cuts off at the head end, runs around the trip, pushes it on the dump where it is turned over at once, and when righted he couples to the empty cars and returns with his empty trip to the face, with a delay of only a few minutes. By this arrangement, for short periods, loaded trips up to three times the rated capacity of the conveying system can be taken care of as they come in.

The bin under the dumps will hold sixteen loaded trips, and with the conveyors running this allows a rapid handling, thus eliminating delays on the haulage system and also keeping all mine cars in motion practically all the time except when being loaded. The coal from Colonial Nos. 1 and 3 enters the dumps from one end, each normally using the dump on its own side, and No. 4 enters at the other end, using whichever dump happens to be empty when the trip arrives. Block sig-

**Double-Reduction Gear Box and Motor Set**

The driving equipment is set in rooms made in crosscuts adjacent to the conveyor, thus keeping all gears out of the main gallery. This conserves space and removes all possible operating hazards.

nals notify the motormen when each dump is clear.

One man handles both dumps and takes care of the signals. The dumps are rotated by compressed air, three 17-in. diameter cylinders being used for the over-turning and two for the reversing of each dump. Power is applied from these cylinders to the rotating cage structure through long H-beam sections and short lengths of wire rope. This eliminates the unequal stretch of long and short ropes used simultaneously.

Belt No. 20, which is 60 in. wide, extends under this hopper and is fed by thirty-four apron feeders which are all in operation at the same time and so designed as to feed a regular tonnage to the belt according to the speed at which they are set to operate. They are all driven by a single variable-speed motor, each individual feeder being driven from a line-shaft which is direct-connected to the driving motor.

Chains from this line-shaft drive worm-gear reducers which, in turn, drive each of these feeders. These multiple feeders give a very even load on the conveying system and, due to the light duty on each, should have a much longer life than could be expected where large tonnage is fed over a single feeder. In conveying 8,500 tons per day, each feeder handles only 250 tons per day.

#### DISCHARGES AT RIVER TIPPLE

At the river or discharge end of this conveying system, a large river tippie was built. The coal when discharged from No. 1 belt passes over a long bar screen with bars spaced to pass coal of a desired size. All small coal is collected in a chute which feeds a shuttle conveyor distributing it uniformly over the entire length of a slack-coal bunker.

The coal passing over this screen is fed to a duplicate shuttle conveyor which distributes it over the lump-coal bunker. These shuttle conveyors are either manually or automatically operated, as desired, and so interlocked with the main system as to start always with the other belts, thus preventing any flooding of coal at the start. Each has a capacity of 1,000 tons per hour, allowing for variations in the quantity of slack in the coal such as at times will occur.

The bunkers are of the suspended type, being suspended over the river from heavy girders resting upon six large concrete piers. Each of these bunkers has a capacity of about 1,200 tons. Coal is taken from the bottom of the bunkers through eight gates spaced so as to feed coal uniformly to a barge 175 ft. long. This allows each barge to be completely loaded without moving. A barge of 850 tons capacity can easily be loaded in ten minutes. The chutes leading from the gates to

the barge are arranged to telescope to allow for varying heights of water in the river.

The gates and telescoping chutes are all operated by electric motors which are centrally controlled in a cabin located beneath the bin where the operative has a clear view of all operations. The gates are opened by torque motors which hold them open as long as the electric current is kept on them. They are counter-weighted so as to close automatically as soon as the current is cut off. Thus in case of power failure the gates immediately close. The operator can open or close all gates at once, or any individual gate or number of gates by simply pressing the proper buttons on his board. A small barge-mover for handling both empty and loaded barges is also operated from this same board. A large reinforced concrete ice-breaker protects this harbor in which space is provided for storing ten empty and ten loaded barges.

#### CONVEYED 9,426 TONS IN ONE DAY

With this general description of the conveying system and its feeding and unloading arrangements, let us look at it briefly from the operating standpoint. It was started in regular operation April 12, 1924 and up to the present time has carried a little over one million tons of coal. The largest day's production up to Nov. 15 was 9,426 tons. The production during the month of October indicates that by this equipment it will be possible to obtain the production contemplated. The power requirements for the month were 0.363 kw. per 100 tons per 100 ft. level or equivalent.

The total power used for operating the conveying system, pumps, fan, and charging storage-battery motors, including transformers and line losses was 338,000 kw.-hr., of which 250,000 kw.-hr. were required for the conveying system.

In the months of August and September power tests were run on all these conveyor units. Each test was for an entire day, and accurate power readings were taken, the time the belt operated loaded and empty and the tonnage handled were recorded. The data shown by Table III is the result of this series of tests. At the time they were made the tonnage was less than is now being carried, but the results should be fairly representative of the power consumption.

From this data a formula has been prepared for cal-

culating the horsepower required to drive conveyors completely equipped with anti-friction bearings of the class being used. This formula applies only to 48-in. belt conveyors of long centers. It is divided into three parts, the power to drive a belt conveyor empty, plus the power to carry a given tonnage a horizontal distance, plus the power to lift this tonnage a given height.

The first part, or empty-belt power, is one of friction, both rolling and bearing, and is not exactly proportioned to length because the loads and belt stresses carried by main bearings are practically constant regardless of length, whereas the carrier rims and belt weight are directly proportional to length. We find from these tests that lift has practically no influence on the power used by a belt conveyor running empty. On conveyors such as are used in this system, the lengths and conditions are so nearly constant that the power per 100 ft. of conveyor is almost uniform, and in this formula we have taken the constant  $K$  which represents the power per 100 ft. of conveyor directly from the data as tabulated. This constant presupposes that all parts of the equipment are in first-class condition.

Its average value on all conveyors in the system having tandem drives is 2.11 kw. or about 2.5 hp. For safely estimating power the value recommended is  $K = 2.8$  when figuring the horsepower of conveyors of this class. The power for an empty conveyor where  $K =$  constant representing conditions and class of equipment, and  $L =$  length of conveyor in feet between centers of head and tail pulleys is given by:

$$\text{Empty Power} = \frac{KL}{100}$$

The second portion of this formula represents the resistance of the live load added to the empty belt which is simply bearing friction and rolling friction of this additional load on the carriers. This portion of the power is directly proportional to the length of conveyor and the tonnage carried and can be expressed as follows:

$$\text{Power for Live Load} = \frac{CTL}{100 \times 100}$$

Where  $C =$  constant power required to carry 100 tons 100 ft.;  $T =$  tons per hour and  $L =$  length of conveyor in feet.

The last portion of the power takes into considera-

\* Demand measured as additional power above empty demand. Difference between preceding columns. † Based on two preceding columns.

tion the direct work of raising this load a given height with an allowance for electrical and mechanical efficiency. This can be expressed as follows where  $H$  = height of lift in feet;  $D$  = constant due to efficiency:

$$\text{Power for Lift} = \frac{DTH}{1,000}$$

Assembling these various components we have for driving conveyors of long centers with tandem drives with all bearings of high class anti-friction type:

$$\text{HP.} = \frac{KL}{100} + \frac{CTL}{10,000} + \frac{DTH}{1,000}$$

For conveyors of this class the value of the constants for figuring horsepower of conveyors is as follows:  $K = 2.8$ ;  $C = 0.18$  and  $D = 1.12$ . This gives safe data for estimating power requirements on conveyors of this class.

Summarizing, it has been found that a conveyor is dependable in its operation; positive in its performance; durable to an extent greater than most machines; less hazardous to life, and not entirely dependent upon the human element. It requires few men to operate; is not excessive in first cost, and has low operating charges.

Typical Inside Switchboard and Starting Panel

To the right in the foreground is the speed-reduction gear. There are three incoming lines on the system any two of which could furnish the whole installation. All motors are 2,300 volt, 3-phase, 60-cycle, 900 r.p.m. and of wound-rotor type. The entire system is controlled from No. 1 motor room.

## Nunnery Mine Accident May Lead to New Laws Relative to Inclines

Seven persons were killed, fifty-five were injured, eight seriously, when a rope on a 1-in-9 incline broke, Dec. 3, 1923, at the Nunnery Colliery near Sheffield, England. A report on the accident recently has been made by Sir Thomas H. Mottram, chief inspector of mines.

The rope was used for bringing coal cars out of the mines, returning them empty, hauling men from the mines and lowering them into the workings. The haulage rope passes to the surface through 4-in. cast-iron pipes which run down the brickwork lining of the shaft. A rope passed from the front car over the top of the trip to the back car to connect the wagons in case any of the couplings broke, and in hauling the cars up the incline a drag was put on the last car. An "authorized person" rode on the trip whenever persons were being hoisted or lowered. No one was allowed on a trip in which coal was being hauled.

On the day of the accident, the set of forty-four wagons of which forty-two were for riding purposes, known as the "Paddy Mail," were attached to the rope, and some 120 persons entered the cars to ride down the incline. The "authorized person," Colin Chappell, passed his knife eight times over the two signal wires to show that the men were in the cars and then four times to order the enginemen (there were two when men were being transported) to lower them slowly. They were usually lowered at a speed of only three miles an hour. For about 40 yd. they proceeded at that speed, but at the end of that distance they began to travel much faster. Chappell gave the four-ring signal again, but the enginemen interpreted it as one ring which required him to stop the trip and this he did. But he had barely done so when the rope parted and the man trip plunged down the incline and left the track at Cain's junction, 377 ft. below the starting place.

When hauling coal only 34 to 36 cars were used, and the average load was 28½ to 30½ tons. When hauling men the car at each end was filled with scrap iron to stabilize the trip, but the dead weight on the rope was only 19 tons. Nevertheless the rope broke, showing

that having pulled a larger load just prior to the lighter man-trip did not insure the men against an accident. The factor of safety with the new rope when lowering coal was 10.3; when raising coal 6.3; when lowering the men it was 14.8 and when raising them 9.0. Tests on the old rope that had been 19½ months in service showed that when lowering coal the safety factor was 5.9; when raising 3.6 and when lowering men it was 8.5 and in raising them 5.2. Other ropes had lasted two years.

Whenever a new length was added to the rope a corresponding length was cut from the capel end. By this process the oldest part of the rope was between the capel and the first splice. It was here the rope broke at a point 70 yd. from that splice and 230 yd. from the capel. The rope had been inspected 2½ hr. before the accident. An inspection seemed to indicate that eight interior wires in three adjacent strands had broken prior to the accident suggesting that the rope had been injured. Only two interior wires had corroded. There was a slight rust throughout but "no excess of corrosion." At the point of fracture the rope had been reduced about 40 per cent in effective area. The cable had been tarred weekly, had received a thorough weekly examination and was inspected daily to detect broken wires, a workman allowing it to run through his hand, a piece of hemp bagging or cotton waste being used to protect the hand from injury. The rope was recapped once a month.

It was shown that, when examinations were made and two or three broken wires were found in one strand, no report was made of the injury to the rope, but a splice of new rope was inserted. No report was made or action taken where only a single wire was broken. The chief inspector said that this practice might have kept the management from learning of the gradual deterioration of the rope, and stated that reports of this character should be made. He declared also that ropes used for the haulage of persons on inclined planes should not be spliced and that such ropes should not be used over eighteen months. He urged that an effective safety device to arrest cars, should the rope break, be placed on every man trip on an inclined plane and that the provision of a separate road for the haulage of men should receive the attention of mine managers.

## Steel-Plant Men Find Welding Has Wide Application

Thermit Welds Supplementing Arc and Gas Welds—  
Can Use Manganese Oxide to Harden Outer  
Surface—A 6,500-Lb. Weld

IF COAL-MINE mechanical and electrical men had attended the monthly meeting of the Association of Iron & Steel Electrical Engineers at the William Penn Hotel, Pittsburgh, Pa., on Dec. 13, they would have learned to what a large extent the various methods of welding are being utilized by the iron-and-steel industry to salvage broken and worn parts of electrical and mechanical machines. This meeting of the association was confined to illustrated descriptions of, and the technique entering into, scores of welding jobs which have been done successfully at the iron-and-steel plants in and about Pittsburgh. As W. L. Warner, of the General Electric Co., put it, "Welding equipment is the iron worker's needle and thread." Judging from what was said at this meeting, the steel plants make wider use of welding equipment than the coal mines.

Three processes of welding are in common use in the steel plants. Two of them, arc welding and oxy-acetylene or gas welding, are widely employed at our coal mines and need no further explanation. The third process, however, is seldom, if at all, used at the mines and should have applications similar to, and also different from, those covered by the arc-welding and gas-welding processes. The process in mind is "thermit welding." The term "thermit" is applied to a mixture of powdered aluminum and iron oxide.

Aluminum has a great affinity for oxygen. Consequently when it is mixed with an oxide of iron in a crucible and ignited by an agent such as a burning piece of magnesium ribbon, a chemical reaction takes place. The iron oxide is reduced to iron and the aluminum combines with the oxygen set free from the former and forms aluminum oxide. This reaction is exothermic and produces a temperature of about 5,000 deg. F. Consequently the iron and aluminum oxide are melted down during the change.

### CAN INCREASE TENSILE STRENGTH

These two products, not being miscible, separate into two layers. As the specific gravity of the molten iron is greater than that of the aluminum oxide, when the contents of the crucible are poured into a mold, the aluminum oxide rises to the top and does not form a part of the welded joint. The tensile strength of the iron in the joint thus formed is equivalent to that of iron laid by any other welding process. By the addition of oxides of alloy metals to the mixture the tensile strength of a welded joint can be substantially increased, and the composition of the welding material may be made similar to the metal being welded. Ten to twelve per cent of manganese oxide may be added to the thermit and it will form a hard outer surface on the welded area.

The thermit process may be used successfully for steel, wrought iron and cast iron. The procedure for each is about the same except that more care must be exercised so as not to overheat the cast iron while it is being welded.

H. D. Kelley, district manager of the Metal & Thermit Corp., Pittsburgh, Pa., described the uses of thermit

welding in the iron-and-steel industry for the reclaiming of broken and worn parts of machinery. The largest welding job ever made to his knowledge was the repair of a shear in a blooming mill of the Pittsburgh Steel Co. The break was so large that 6,500 lb. of thermit were required to effect the weld. He briefly described another interesting job: At one of the blooming mills of the Carnegie Steel Co. a broken crankshaft, of 27-in. diameter was reclaimed by thermit welding. In this job a new end was added to the shaft.

Mr. Candy, of the Westinghouse Electric & Manufacturing Co. and W. L. Warener, of the General Electric Co., described many steel-mill repair jobs in which the electric arc welder played the most important role. Don McCloud, consulting engineer of Chicago, described the manufacture of oxygen by the liquefaction method. Incidentally he mentioned the welding by oxyacetylene, in an oxygen plant, of a  $\frac{3}{4}$ -in. seamless tube pipe line which withstands a pressure of 3,000 lb. per sq.in. Mr. Applegate described the oxyacetylene welding of a 28-in. exhaust-steam line at one of the mills. He said the welding of joints eliminated rivets and rivet friction and allowed the use of a pipe line of smaller diameter.

### WELDING FOR MINE REPAIR JOBS

A list of a few of the many repair jobs that are made in steel mills by welding should convince our mine repair men of the value of welding. These are set down without further explanation, as follows: Shafts of all sizes and of various designs, including armature shafts; frames and housings on large and small machines; flywheel spokes; racks; gears and pinions—helical and spur—; hydraulic cylinders; pipe joints; locomotive frames; switch points, track frogs and crossovers; connecting rods; locomotive-wheel flanges; boiler flues and tanks of all kinds.

The meeting brought out the following facts that should be helpful to the repair men at the mines: Thermit mixture, the material used in thermit welding may be so composed that the product of chemical reaction in a weld joint is a metal which closely resembles the metal of the parts that are joined. Manganese oxide may be used in the thermit crucible or sprinkled on an area being arc-welded to produce a hard wearing surface, a suggestion particularly valuable to mining men who desire to build up worn switch points, frogs and crossovers. The addition of granular nickel to a weld may add as much as 5,000 lb. per sq.in. to its tensile strength. There is no practical limit to the application of welding methods. Its practicability extends from  $\frac{1}{8}$ -in. sheet steel to huge shafts and frames, for if a welded joint holds on a small job it should hold on a large one. Broken taps may be welded together allowed to cool and then backed out from the holes that are being threaded thereby saving much time. Extensive fractures in locomotive frames may be repaired by cutting out a section and joining the two ends by layers of steel plates welded together. Worn armature shafts can be built up without having to tear down the armature itself. Steel structural members in buildings are often joined by being welded instead of by riveting. This suggests a practice that might be followed in the erection or repair of tipples and other structures subject to vibration. A good welding job will generally give as long a life to a broken part as that possessed by a duplicate new part.

# West Virginia-Kentucky Electrical Men Present Their Problems and Experiences

Floating Battery Irons Out Frequently Recurring Peak—Such Accumulators Have Long Life—  
Use of Storage Batteries as Auxiliaries—How to Convert the Mine Foreman—  
Rotary Converter Versus Motor-Generator Set

BY A STAFF CORRESPONDENT

**S**PIRITED discussion characterized the fourth annual convention of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, held at Huntington, W. Va., Dec. 12 and 13. No exhibit was held in connection with this year's meeting but nevertheless there was a sufficient attendance at all sessions to make the convention a success.

In opening, R. R. Webster, of Weeksbury, Ky., who is president of the association, called attention to the unfortunate fact that at no time is it more difficult for men to get away to attend meetings than just when the mines most need to reduce the cost of production by improved and more efficient methods, and therefore when a getting together of the electricians and mechanics to iron out difficulties is most desirable they are either too busy to come or the company hesitates at the small expense that their attendance would incur.

The paper prepared by Byron B. Minnium, on voltage control in mines by storage batteries evoked an interest which was evidenced by lengthy discussion. Mr. Kennedy, of the Electric Storage Battery Co., described two installations in Illinois mines. In one of these instances batteries have been used for three years to help handle the peak load caused by a main haulage locomotive pulling a trip up a short 4-per cent grade which is about 5,000 ft. from the shaft. For this purpose several old batteries, which have already served their best days in mine locomotives, are connected so as to float on the line taking charging current only when the load is light and delivering high current back to the line when the demand is heavy. The installation of this battery in the mine, near the point of heavy grade, raised the minimum voltage delivered to the 13-ton locomotive from 75 volts to 175 volts.

The other use of batteries which he described was at a mine which was shut down for a long period. This operation has its own power plant and is equipped with battery locomotives for gathering. By using the locomotive batteries to operate the fan and pumps it was necessary to operate the power plant but one day per week. On this day the batteries were charged and any necessary heavy work done, such as using locomotives for the general upkeep of the mine. The batteries had to be charged and care had to be given them regardless of use, so that the arrangement described did not incur any additional labor.

In regard to the life of a battery floating on the line, J. H. Markham, of Ronda, W. Va., called attention to the fact that batteries thus used should have a longer life than if incorporated in the frame of a mine locomotive. The floating battery being at a state of full charge most of the time, the tendency to sulphation and other deterioration of the plates would be reduced.

Replying to questions regarding the efficiency of a floating battery, and as to the highest discharge rates possible for short periods, Mr. Kennedy replied that a 92-per cent ampere-hour efficiency has been obtained in such service, and that discharge rates of 10 or 12 times normal rate are quite practicable.

E. W. Pardee, of Charleston, W. Va., inquired whether in any instances batteries are being used as auxiliary power sources for the operation of mine fans. Mr. Caverlee said that a 130-cell, 23-plate battery, after having been used at an Ohio mine as an auxiliary on a fan for over four years, was examined and found to have deteriorated but little during this long period of use.

A. F. Brosky, of Pittsburgh, described an installation in the Fairmont field where a cable was run through a borehole from the fan to the underground motor barn. In case of power failure a battery locomotive is ordered into the barn and connected, through the cable, so as to furnish power for the fan motor.

An important emergency use for which a locomotive battery should be kept in mind was described by Mr. Webster, this for excitation in a mine power plant where alternating-current generators are used. In getting generators back on the line after a shutdown, temporary operation of the steam-driven exciter is necessary. If at this time the exciter should break down, then a 40- to 60-cell locomotive battery can be used temporarily to furnish generator field until the motor-driven exciter is started.

At this point the discussion digressed to the subject of electrification of gaseous mines by storage batteries. The recent paper on this subject read at the West Virginia Mining Institute by John B. Hicks of the Consolidation Coal Co., formed the basis of this discussion. Using a large battery mounted on a truck and assigned to a mining machine for furnishing power for cutting is the radical departure which is attracting attention. The more important advantages, aside from the primary feature of being able to use electricity

with greater safety in a gaseous mine, were recounted; these being, increased speed of cutting because of improved and constant voltage, elimination of delays caused by power interruptions, elimination of bonding expense, elimination of trolley wires, and reductions of peak loads which under certain rate schedules effects a large saving in the demand portion of the power bill.

W. H. Miller, Jr., called attention to the large investment in batteries which is necessary when power is to be furnished for cutting, gathering and hauling, and to the fact that in from three to five years the batteries will be worn out and the investment must be duplicated.

F. A. Signer, who was to have given a talk at the meeting on the methods of the electrical department of the Southern Mining Co., found at the last moment that he would be unable to attend, so he sent a message requesting the chairman to ask J. H. Edwards, who is familiar to a certain extent with their methods, to describe these in a general way. The Southern and associated companies hold, about twice a year, a meeting of their chief electricians. As many as possible of the mine foremen and superintendents also attend. The electrical department costs of each mine are reviewed and discussed. Each chief electrician is asked for a report covering his success or troubles with the different kinds of equipment in use at the mines, and concerning plans he has to propose for lowering the costs of electrical operation. Naturally many matters are discussed which concern the foremen and superintendents, hence the advantage of their being in attendance.

The foregoing account of the Southern Mining Co.'s methods was followed by a general discussion of the ways of obtaining closer co-operation between the mine foremen and electricians. R. R. Webster called attention to the fact that many mine foremen seem to forget that abuse of equipment and the resulting repairs add to the cost of coal at the mine and so reflect unfavorably on their management of the company's property. The days of "production regardless" seem to be over; this is a time of lower cost per ton.

The idea was advanced by F. M. Reigher, of Bluefield, that the mine electrician himself is to blame for much of the lack of co-operation of which he so often complains. The mine electrician needs to exercise more patience and perserverance. W. H. Milton, Jr., said that a large anthracite mining company has found that the holding of regular, combined meetings of electricians and mine foremen is the best way of impressing upon foremen the necessity for using more consideration in the operation of equipment.

Reducing costs by proper supervision of mechanical and electrical equipment was the subject of a paper read by J. H. Edwards. This was illustrated by exhibits and punctuated by citations of actual instances where electrical men effected appreciable savings in

production cost and of other instances where an opportunity to make a saving was not recognized until too late. J. H. Markham stated that, as a rule, the mine electrician is kept with his "face so close to the grindstone" that he cannot see and remedy many of the important opportunities that are within his grasp. A. F. Brosky recalled that the large steel companies found long ago that they can afford to spend more for inspection and engineering supervision of equipment than for actual repairing.

The importance of keeping in stock small inexpensive repair parts, which are difficult to obtain on short notice, was discussed by T. A. Martin, of the Peerless Coal & Coke Co., Vivian, W. Va. He cited a large coal company which, in order to facilitate ordering repairs, obtained from the equipment manufacturer duplicate name plates for each item of equipment, and filed these plates in the engineering office for reference. In regard to pump installations, Mr. Martin stated that slate falls on the pipe line close to a pump frequently broke the water-

end casting, so the Peerless company is now using a short length of hose adjacent to the pump, in both the suction and discharge lines.

H. H. Fletcher, manager of the Quincy Coal Co., Quincy, W. Va., said that he thought the greatest opportunity to make a saving in maintenance expense exists in periodic inspection and prompt repair of all the small items. He favors the purchase of insurance against electrical breakdowns. This causes more thorough inspection, and assures the company that faults when reported

will be repaired promptly in order to avoid paying a penalty in the form of a higher premium.

The ordering of repair parts as soon as the need can be foreseen was urged by Mr. Pardee. Waiting until the last moment and then ordering an express shipment by telegram is expensive. An actual case was described where a new set of tires for a locomotive were ordered from the factory by express. These were needed to replace worn tires, and the need could have been anticipated a month, or perhaps, several months.

E. L. Hough of the General Electric Co. gave a short talk on automatic substations. This was followed by the showing of a new film illustrating installations in coal and salt mines. The step-by-step operation of the relays and automatic contactors was shown in detail. R. R. Webster inquired if satisfactory apparatus is available for the automatic paralleling of two machines located in the same substation. To this Mr. Hough replied that there is little difficulty in paralleling converters, but much difficulty in paralleling motor-generators which are over-compounded. The difficulty arises when a cold machine is added. As it warms up, the percentage of load which it carries will change materially unless the field rheostat is adjusted. A current balance regulator is now available which does this automatically.

---

**S**TORAGE batteries have many other uses besides those of driving gathering locomotives. Their ability to help in meeting mine problems seems now to be receiving unusual attention as was evidenced by the discussion at the meeting of the West Virginia-Kentucky Mine, Mechanical and Electrical Engineers. As usual the inability of the mine foreman to visualize the importance of the careful use of electrical equipment was a subject of extensive comment. Nothing or little was said apparently about ineffective bonding. Is it to be concluded that this defect has been largely removed in the states principally represented? If so the companies whose electrical men were present are to be congratulated and their electrical experts to be commended. Would it were so everywhere!

---

F. M. Reigher stated that he had overcome the trouble of paralleling motor-generators, by using machines which are designed for flat compounding. He followed this discussion by reading an instructive paper in which the rotary converter was compared with the motor-generator. He carefully analyzed the characteristics of each and compared the costs of manual and automatic types. He stated that the overall efficiency of a converter installation is from 5 to 8 per cent higher than that of the motor generator. Except for the one big feature of power-factor correction, the converter seemed to get the best of the argument in the lively discussion which followed Mr. Reigher's paper.

Roscoe Woltz called attention to two advantages of the converter which were not mentioned. The pull-out torque is about 4 times the rated load, as compared to about  $2\frac{1}{2}$  times for a motor-generator. Also in case of the failure of a bearing, a replacement is readily made on a converter, but may be complicated on a motor-generator, because in a three or more bearing outfit the question of shaft alignment must be considered.

J. H. Edwards called attention to the necessity for an automatic field regulator on synchronous sets to maintain a desired power factor. Mr. Hough stated that two such automatic regulators are now in use at Pennsylvania mines.

Following the discussion of Mr. Reigher's paper, the subject of electric welding for shop repairs was considered. Mr. Webster described a number of useful applications and reviewed a year's experience in filling worn locomotive tires. His conclusion, based on his experience to date, is that welding tires does pay, but that the margin of saving is small, therefore the most economical methods must be used. He uses a  $\frac{1}{4}$ -in. diameter Wanamaker manganese-steel electrode, and grinds the filled-in surface by a home-made device which requires little attention.

Answering a question by Mr. Fletcher, as to the direction in which the layer of metal is laid, Mr. Webster stated that the beads are applied crosswise to the length of the tread. Mr. Markham said that

his experience indicated that in a plain sleeve bearing a built-up shaft seemed to wear just as little as, if not less than, the original material.

The discussion of correct methods of installing feeders in boreholes was opened by the reading of a paper written by E. S. Simpkins, of Pittsburgh, representing the Standard Underground Cable Co. He described their lead-covered, steel-wire-armored cable and the method of supporting it at the top of a borehole by a long clamp around the armor. For a cheaper installation a varnished cambric two- or three-braid weather-proof cable is recommended. He also advocated that it be supported by carrying it over a sheave of large diameter, or in case of high voltage that each conductor be tied to a separate strain insulator.

W. H. Milton, Jr., told how, in lowering jute-covered cables into deep boreholes trouble is encountered because the jute covering is pulled off by the impregnating compound causing the turns on the reel to stick together due to the weight and tension. This is overcome by ordering the cable without any compound in the jute covering, and then applying the compound to the cable, a few feet at a time, as it is lowered into the borehole.

The meeting was closed by a discussion of the correct application of carbon brushes. H. C. Harker, of Huntington, representing the National Carbon Co., stated that abrasives are undesirable in brushes, however if the mica is not under-cut, a degree of abrasiveness is necessary. He described the arc type of slotting for commutators. With this type of slotting less dirt collects than with any other, but it requires special tools. Mention was made of experiments which are being made of using a varnish in the slots after cutting. It is believed that this will prevent oil or moisture from damaging the mica.

Mr. Webster condemned the deep, square-bottom slots cut by some manufacturers in their commutators. In the duty encountered in a mine, such commutator slotting often causes trouble due to the arcing in the bottom of the slot, which is a result of an accumulation of dirt, oil and moisture. H. H. Fletcher said that, in his opinion, there are no instances around the mines where proper slotting is not advisable.

#### Orkney-Warwick Mine

This mine is located at Hemphill, McDowell County, West Virginia, about two miles from the business section of Welch in a westerly direction. It is one of nine operations of the Kingston-Pocahontas Coal Co., formerly the Solvay Collieries Co., a subsidiary of the Semet-Solvay Co., of Syracuse, N. Y. The coal is shipped over the Norfolk & Western R.R.

## News Of the Industry

### Green Named as President Of Federation of Labor; To Follow Gompers' Policy

William Green, secretary and treasurer of the United Mine Workers of America, was chosen on Dec. 19 to be president of the American Federation of Labor to succeed the late Samuel Gompers. Soon after his election Mr. Green announced that it would be his purpose to adhere to those principles of trade unionism so ably championed by Mr. Gompers and upon which the superstructure of organized labor rests.

Mr. Green's election took place at a meeting of the executive council of the Federation, held in New York City, and was unanimous. At the same time James P. Noonan, of the International Association of Electrical Workers, was elected eighth vice-president.

The new president of the Federation is 51 years old and lives at Coshocton, Ohio. He has been identified with labor organizations for many years and served at one time as president of the Ohio organization of the United Mine Workers. He has been secretary of the International organization since 1912, when he was appointed by John P. White to fill an unexpired term as secretary.

#### Feels Solemn Duty to Serve

Following his election Mr. Green said that he regarded it as a call to service, "and for that reason I feel it my solemn duty to accept and to serve."

Continuing, Mr. Green said that "the high standard of excellency in service, efficiency in leadership and administrative ability attained by Mr. Gompers during his long and useful career is a challenge to the best and highest of everything which any human being can give in the service of his fellow man."

"While organized labor feels most keenly the loss of the great leader, Mr. Gompers, every member may take courage and consolation from the fact that he left us a legacy of incomprehensible value. We have his trade union creed, his trade union philosophy, his writings, letters and recorded spoken words. All of this will serve as a guide in charting and shaping our course and in the formulation of our policies."

"In co-operation with my colleagues on the Executive Council of the American Federation of Labor and the chosen officers of all affiliated organizations we will carry forward the work of organization and education among the workers of our land."

"We will endeavor to promote collective bargaining, the observance of wage agreements and the acceptance of the organized labor movement by all classes of people as a logical, necessary moral force in the economic, industrial and social life of our nation."

"While striving for the attainment of these praiseworthy purposes we

William Green

Secretary and treasurer of the United Mine Workers of America, who has been chosen to succeed the late Samuel Gompers as president of the American Federation of Labor.

shall ever be mindful of our duties and obligations as American citizens. Our devotion to America and American institutions must never be successfully challenged. Our demand upon society for higher standards of life, better wages, independence and humane conditions of employment must ever be based upon our inalienable right to the enjoyment of life, liberty and the pursuit of happiness.

"Our problems must be met and solved upon the basis of American fair play and in accordance with American traditions and American ideals."

#### Wise Choice, Says Lewis

Later in the day John L. Lewis, president of the miners' union, who came to New York to attend the funeral of Mr. Gompers, issued a statement regarding Mr. Green's election in which he said:

"The election of William Green as president of the American Federation of Labor is the choice of wisdom. Mr. Green's long experience in the trade union movement, his undoubted talent

#### Hard On Hootch

Employees of the Colorado Fuel & Iron Co., which operates a steel mill at Pueblo, Colo., and 26 mines in various parts of the state, will be watching their steps hereafter. Those with thirsts or the where-withal to satisfy the thirsts of others will be especially watchful. The company has posted a notice warning that any employee caught buying or selling "moonshine" will be suspended from the payroll for the first offense and summarily discharged for any repetition, without waiting for a court verdict. The popularity of the Colorado Fuel & Iron Co. among "drys" has risen 8,000 per cent. Prohibition enthusiasts are writing letters to the newspapers about it, saying that if every employer in the country followed this company's example the Volstead law would be enforced.

for leadership and his prestige as a public spirited citizen are qualifications which insure the success of his administration. He is the one outstanding figure who can take upon himself the mantle of the revered Gompers and be assured of the co-operation and devotion of the great majority of the membership of the American Federation of Labor.

"His ascendancy to the position of president marks the beginning of a new era of constructive progress in the ranks of labor and his election will allay any public apprehension that the long established and proper policies of organized labor were to be seriously impaired."

"Mr. Green will enter upon his new duties under conditions which augur well for the future of organized labor and the proper protection of the public interest."

#### Green to Make Few Changes

Mr. Lewis announced that he will soon appoint a successor to Mr. Green as secretary and treasurer of the miners' organization. Mr. Lewis was a candidate for president of the Federation against Mr. Gompers in 1920.

Mr. Green said he intends making few changes in the personnel of the national headquarters staff. He will preside for the first time over the Executive Council at its meeting to be held in February at Miami, Fla.

Following the election of Mr. Green, James Duncan, who for thirty years has been a vice-president of the Federation, tendered his resignation. The resignation was tabled until the meeting at Miami.

## Connellsville Independents Return to 1920 Scale; to Fire 2,500 Ovens

A number of independent coal and coke operators in the Connellsville (Pa.) region on Dec. 15 announced a return to the wage scale of Sept. 1, 1920, the peak scale of the region. Some made the change effective immediately, the others making Jan. 1 the date for putting it into effect. It is probable that others will take similar action around the first of the year. Under the new scale, drivers in shaft mines, track layers and timbermen get \$7.55 a day and assistants \$6.55, with other mine work in accordance.

On the heels of this announcement came orders to fire up immediately 2,438 more ovens in the Uniontown district, giving 3,000 men employment.

Companies that made the new scale effective last week include W. J. Rainey, Inc., Hillman Coal & Coke Co., Connellsville Central Coal & Coke Co., Monessen Coal & Coke Co., Reliance Coke Co., Fayette Coke Co., Puritan Coke Co., Eastern Coke Co., Orient Coal & Coke Co., Republic Iron & Steel Co., Oliver-

Snyder Steel Co. and the Buckeye Coal Co. The Jan. 1 list includes the Snowdon Coke Co. and the Century Coke Co.

The Bourne-Fuller Coke Co., near Searight, was the last to cut wages and the first to go back to the 1920 scale.

The H. C. Frick Coke Co. has issued orders to fire the following ovens immediately: Leith, 300; Brownfield, 200; Dearth, 300; Leisenring No. 1, 500, and Youngstown, 250. W. J. Rainey, Inc., gave directions for immediate resumption at these plants: Allison, 493; Revere, 206, and Mount Braddock, 135.

On Dec. 12 the men at the Republic Mine of the Republic Iron & Steel Co. struck, demanding restoration of the Frick scale (the peak wage). The company thereupon closed the mine indefinitely and resumed operation at its Russellton No. 1 mine, in the Freeport field. The Hillman Coal & Coke Co. has resumed at the Pike Mine, a union operation at Brownsville, on the edge of the union field.

## Engineers to Co-operate in Reforestation Program

Studies of the forestry situation in the various states are to be made by national and local engineering societies under the direction of the American Engineering Council, which announces its purpose of working with the federal government to carry out the provisions of the Clarke-McNary Act.

The nation's timber resources are thinning so rapidly as to constitute a grave social and industrial menace, according to the Council. At a forum in Washington, D. C., Jan. 16-17, to be attended by delegates from all over the country, plans for nation-wide reforestation effort will be publicly discussed.

The Council has appointed a Committee on Reforestation, which has already begun the work of enlisting engineers in every state in a permanent organization whose investigations shall harmonize with the government's policy, according to the president of the Council, Ex-Governor James Hartness, of Vermont.

A survey has disclosed that fourteen states are without forest departments. The most heavily timbered of these are Florida, South Carolina, Georgia, Mississippi and Arkansas. Summarizing what is being done by the several states, a statement by the Council says:

"In November citizens of California will vote on a constitutional amendment placing immature forest growth on the tax exempt list for four years after planting.

"Wisconsin will vote on an amendment which provides for the participation of the state in acquiring, preserving and developing forests and for appropriating funds for this purpose within certain limits.

"In South Carolina a committee representing lumbering, agriculture and other industries is fostering the introduction of a bill providing for a state forestry department.

"Pennsylvania will vote in November upon the issuance of \$25,000,000 in bonds to be used for the purchase of state owned forests. A conservation council composed of interested organizations is ardently supporting this issue.

"The State Land Board of Oregon is expected to approve the exchange of numerous isolated sections of timbered school land for a single tract now under control of the federal Forest Service.

"Idaho chambers of commerce are campaigning for a state forest policy which will obtain federal co-operation under the Clarke-McNary bill. A similar activity is under way in Arkansas.

"In Georgia the Rowntree-Haddock bill, providing for a state forestry department and a forest fire protection system failed to pass in the last session of the Legislature. It will be introduced at the next session."

"The Council," said ex-Governor Hartness, "will enlist the co-operation of all interested organizations in every state in carrying on a campaign to effect the passage of such legislation and changes of forestry policy as will enable the state to co-operate fully with the federal government in carrying out the provisions of the Clarke-McNary Act."

## Supreme Court Denies Writ to Pennsylvania Mining Co.

The U. S. Supreme Court on Dec. 15 denied a writ of certiorari sought by the Pennsylvania Mining Co. to review a decision of the Eighth Circuit Court of Appeals in reversing and remanding for a new trial by the federal District Court at Ft. Smith, Ark., a suit brought by the company against the United Mine Workers of America and others.

This suit is a companion to the famous Coronado Coal Co. case. Alleging that the union had interfered with interstate commerce by obstructing operations at its mine in Johnson County, Ark., the Pennsylvania Mining Co. brought suit for triple damages under the Sherman anti-trust law. A jury in the District Court awarded \$100,000 in 1920, and judgment for treble this sum was entered. The union appealed. Meanwhile the Coronado case, along similar lines, went to the Supreme Court, which decided that interstate commerce had not been affected. On retrial of the Coronado case the lower court gave a verdict for the defendant union. The Coronado company appealed. Both this latter appeal of the Coronado company and the appeal of the union from the verdict in favor of the Pennsylvania company were argued before the Eighth Circuit Court of Appeals last July, as similar issues were involved. The Circuit Court of Appeals, affirming the decision dismissing the Coronado case—that company appealed again to the Supreme Court—reversed and remanded for a new trial in the District Court the case won by the Pennsylvania company, using the Supreme Court opinion in the original Coronado case as a precedent.

The petition of the Pennsylvania company for review by the Supreme Court was denied because the decree of the Court of Appeals was not a final judgment, the case having been remanded for further action in the District Court.

## Non-Union Competition Closes Florence Mine

With the ending of work on Saturday evening, Dec. 13, 250 miners employed by the Rochester & Pittsburgh Coal & Iron Co. at the Florence mine, Delancey, Pa., were thrown out of employment. When the men reported for work on Monday morning they found a notice posted at the mine announcing that the mine had been closed because the present union scale of wages made it impossible to compete with non-union mines.

The announcement was signed by the president of the company, B. M. Clark, who also is president of the Central Pennsylvania Coal Producers Association. Mr. Clark recently had several exchanges of letters with John Brophy, district union president, on the advisability of modifying the Jacksonville wage agreement in order to rehabilitate the coal industry of central Pennsylvania.

Every mine of the Rochester & Pittsburgh Coal & Iron Co. is now idle. Several months ago other mines were closed and the working was concentrated in the Florence mine, which is said to be a low cost mine. However, the company does not see its way clear to continue operating at a loss.

Officers of the company feel that if the United Mine Workers in the central Pennsylvania field would save itself from disintegration it must meet the operators of the district and agree upon a scale of wages that will enable the operators to meet competition. Otherwise it will only be a short time until none but open shop mines will be running and there will be no financial resources upon which the union may rely. Of the approximately 30,000,000 tons of coal produced in the field since April 1 of this year only a little over one-third came from the union mines.

## Hoover Peace Means Death For Pennsylvania Mining, Charles O'Neill Declares

"Unless production costs are revised, mining in central Pennsylvania may soon be a lost art," declared Charles O'Neill, secretary of the Central Pennsylvania Coal Producers' Association, in answer to Herbert Hoover, Secretary of Commerce whose aid was solicited in effecting a modification of the wage agreement obtained through his intermediation at Jacksonville, Fla. Mr. O'Neill declares that the peace Secretary Hoover seeks is the peace of death for the Pennsylvania operators and miners.

Continuing, Mr. O'Neill says: "Many of the mines in our district for nearly a year have been losing heavily. The operators have seen their markets torn away by other districts and have been able to hold old customers only by selling fuel at a price that is considerably less than the cost of producing it. Obviously, this course cannot be continued indefinitely.

"Secretary Hoover declares that eventually this will be beneficial to the industry, since he declares that many mines should be abandoned. We of the central Pennsylvania field do not feel that we should be the victims of the program. Neither do we believe that it will work out as Secretary Hoover predicts it will. For every mine that is closed in Pennsylvania a new mine is being opened in West Virginia and Kentucky. At the end of three years of peace there probably will be more mines and miners than there are today but they will be in the South.

### Southern Mines Gaining

"Ten years ago central Pennsylvania produced 15 per cent of the soft coal consumed by this country. Today our production is about 8 per cent. In the same period production in the Southern field has increased tremendously. Today West Virginia and Kentucky are sending coal into Eastern markets formerly held by the central field. We believe the cross hauling is uneconomic to the highest degree. It imposes an unnecessary burden upon transportation facilities of the country and at the same time is an injustice to the central Pennsylvania operators, who have hundreds of millions of dollars invested in their plants.

"Coal is being produced in West Virginia at a cost so much under that produced in Pennsylvania that the operators in the former state can absorb the difference in freight rate to the great Eastern consuming centers and still undersell Pennsylvania coal.

"We contend that this is an unwise and uneconomic condition. Coal should be consumed at points as close as possible to the sources of production. If Secretary Hoover's program resulted in the elimination of mines and miners, it might have some justification."

Mr. O'Neill gives further reasons why the policy is wrong and continues: "We have endeavored to demonstrate to Mr. Hoover that it is contrary to sane national policy to drive coal mining out of a large section of Pennsylvania. The coal here is of exceptionally high grade and should be

## Maybe It Was a Pocket Of Gas

A new financial hazard for coal operators may be presaged in a damage suit recently filed by a Pittsburg (Kan.) boy, through his father, against the Western Coal & Mining Co. The boy says he picked up a pocketful of powder at one of the Western mines, and that later that day, while hunting with some other boys, the powder caught fire in his pocket and he was burned. The father accuses the company of negligence, and asks \$3,000 damages.

utilized in its natural consuming territory, which is the eastern Atlantic and New England states."

Mr. O'Neill then points out the disadvantages of allowing Southern coal to undersell and move across the mines in Ohio to lake ports, move across Illinois to upper Mississippi points and be accorded rates that make it possible to enter the Southwest through the St. Louis gateway.

He then says: "It is thus easily seen that the old established mines in the greatest producing territory in the whole country are slowly but surely being destroyed by competition from Southern fields made possible because Secretary Hoover seeks to permit economic forces a free play for a number of years which an arbitrary factor prevents.

"We are asking our miners to accept a wage scale that is established in West Virginia and Kentucky plus whatever freight differential may exist between those states and Pennsylvania. If this proposal is accepted, the mines of Pennsylvania can continue in operation, and they also will recapture much of the business that has been lost during the past year."

## Wants More Mine Guards In Western Kentucky

Authority to use extra federal guards in the western Kentucky coal mining district to enforce an injunction against striking union miners was requested in a telegram Dec. 20 to Attorney General Stone by L. E. Barnes, chief Deputy United States Marshal at Louisville.

An attempt to dynamite the home of Robert Rolin, superintendent of the Rockport Coal Co., at Centretown, Dec. 19, is believed to be the cause. Details are lacking because of broken telephone or telegraph lines, but it is understood that no members of the Rolin family were injured. Windows were shattered.

A temporary injunction was granted in federal court at Louisville Dec. 18 against thirty-eight union officials, including local union heads in Muhlenberg County, following charges by the Roger Brothers Coal Co., of Bevier, that striking union men intimidated non-union workers on company property.

State officials endeavoring to investigate the dynamiting were handicapped by inability to obtain information from Centretown.

## Decries Quack Remedies for Industrial Ills

That the recent repulse of radicalism by the English-speaking peoples on each side of the Atlantic shows encouraging progress in political sanitation was one of the points made by James A. Emery, counsel for the National Manufacturers' Association, in the course of remarks at a luncheon in Washington, Dec. 17, at which the Smokeless Coal Operators' Association was host. The radical movement in the United States was compared with the quack in the vending of his wares on the street corner, where the audience is large but purchasers few. Despite the advertising, pink pills for a pale nation failed to sell.

While Mr. Emery said some producers should talk less about their rights and think more of their obligations, he declared there is less excuse at present for the intervention of government authority in the conduct of such an industry as is coal production than ever before. It is plain, he declared, that the public wants intervention in the territory of business to proceed no further.

The luncheon was a feature of an association meeting, at which officers were elected for the ensuing year. William D. Ord, president of the Empire Coal & Coke Co., of Landgraff, W. Va., was elected president; William C. Atwater, of New York, first vice-president; W. D. Tams, Jr., of Tams, W. Va., second vice-president; G. H. Caperton, treasurer, and E. J. McVann, secretary.

The bylaws of the association were amended to permit of the appointment of an additional member to the board of directors, so as to provide representation for the new Greenbrier Operators Association. E. S. Simpson was selected to represent the association on the board. The Pocahontas Association will be represented on the board during the coming year by T. S. Farrell and L. Rodman Page, Jr.; the New River Association by G. H. Caperton and Holly Stover; the Winding Gulf Association by W. Gaston Caperton and P. M. Snyder. The directors for the Tug River Association could not be designated until after the meeting of that organization.

The membership committee for the next year will consist of E. White, W. C. Atwater and M. L. Carbey. The transportation committee is to consist of T. S. Farrell, Oscar M. Deyerle and S. C. Higgins.

Coal to the extent of 271,186 tons was used in connection with the manufacture of dyestuffs and tanning materials during 1923, according to the Bureau of the Census. Similar figures covering other industries are as follows: Flags and banners, 1,422 tons; wood, turned and carved, 25,434 tons; cotton-lace goods 66,569 tons; asbestos products, not including textiles, 53,801 tons; sponging and refinishing of cloth, 1,962 tons; paints and varnishes, 83,962 tons; wooden packing boxes, 52,678 tons; paving materials, 542,409 tons; photographic apparatus and materials, 170,417 tons.

## Greater Activity by Labor in Politics Presaged by Death of Gompers

Powers of Leadership, Keen Intelligence and War Work Soften Critical  
Shafts Against Dead Leader—Policy Vindicated by  
Result of Recent Election

By PAUL WOOTON  
Washington Correspondent of *Coal Age*

The death of Samuel Gompers has peculiar significance to those engaged in coal mining, an industry in which the matter of labor relations constitutes its most acute problem. It is interesting to see how public opinion usually changes after a man's death. Mr. Gompers has been as bitterly attacked, at one time or another, as were Woodrow Wilson or Henry Cabot Lodge. Judging from the newspaper comment his death, as in the case of Wilson and Lodge, has softened the asperities of criticism.

Samuel Gompers always was recognized by those who opposed him as having great power of leadership, of possessing keen intelligence and a great facility of expression both by word and by pen.

The death of labor's leader calls to mind again that he rendered the country a great service during the war. There was nothing of the pacifist in his makeup. At no time was there any suspicion that he was in any way pro-German. He hated Bolshevism and Bolsheviks, and particularly the parlor variety. The remarkable speed with which the man-power of the country was mobilized was due in no small degree to the hearty support of the plan by the president of the American Federation of Labor.

The death of Gompers had been anticipated for a long time before the actual arrival of the Grim Reaper. It had been the source of much speculation. For many years it had been accepted as a matter of course that Gompers would remain president of the American Federation of Labor as long as he lived. For that reason all of the plans for changes in the Federation's policies have been predicated on the assumption that they would be launched after Gompers' death. Gompers was a thorough-going conservative. He was as thoroughly opposed to social nostrums as were the captains of industry. There has been no more bitter critic of Red Russia.

Not only that, for Mr. Gompers was entirely out of sympathy with those who, like Ramsay MacDonald, would draw labor into partisan politics. His whole philosophy was to build up a collective bargaining power of labor and work for such immediate ends as higher wages, better working conditions and shorter hours through the exercise of that bargaining power.

He had no sympathy for a separate labor party. The intensity of his convictions on that point resulted from his vivid personal experiences in his early days, when he was identified with the unsuccessful Knights of Labor. This organization in the eighties attempted to improve the condition of labor through acquiring political positions. They failed in their political efforts and, having no achievements to show

the rank and file of labor, the organization quickly lost its hold on the workers and fell to pieces.

The American Federation of Labor was a reaction against this overambitious policy. Gompers was convinced that the way to get ahead was to concentrate on such concrete objectives as the eight-hour day, higher wages and workmen's compensation. All proposals to weld labor into a political machine brought forth anathema from Gompers. He urged the unions to judge each candidate according to his attitude toward their immediate objectives. His policy was to help those who befriended those policies and to work against those who opposed them, regardless of party. The success of this policy in obtaining such objectives as higher wages, shorter hours and better working conditions has been so conspicuous that it bids fair to be labor's permanent policy, particularly in view of the débâcle which followed a departure from that policy forced upon Gompers during the last campaign.

### Was Against Partisan Politics

It was impossible for even as dominant a character as Gompers to withstand altogether the tide which had swept labor in Germany, France, Great Britain and other countries into one political party. Temporary advantages which had come to labor in Europe greatly strengthened the case of those who urged the American Federation to adopt a similar course. Gompers finally, against his better judgment, was prevailed upon to allow the majority view to prevail.

Despite the complete failure of labor's effort at the last election and the evidences of weakness in the labor parties abroad which have been revealed since labor decided to go along with Senator LaFollette, it is known that the death of Gompers is to see a determined struggle to change the policy of the American Federation of Labor from that advocated by Gompers to that of establishing a political machine over which labor will have entire control. There is no reason to believe that such an effort will prevail. The reversal of the Gompers policy during the last campaign proves to have been the most effective step that could have been taken to confirm it. It furnished a striking vindication of Gompers' traditional position. Had he deliberately planned to spike the proposed change it could not have been done more effectively.

If such an effort were to be successful conditions certainly favored it last summer. There was widespread discontent among the farmers. For that reason more of them were willing to join with labor in a political effort than ordinarily would be the case. The

F. F. Sharpless

Secretary of the American Institute of Mining and Metallurgical Engineers. Snapped by W. E. E. Koepler on the Birmingham trip of the institute while the doctor was in deep cogitation.

United States with all of its manufacturing presents no such conditions as exist in Great Britain, for instance. Despite industrial growth the small farmer continues to occupy a dominant political position. His interests as a rule are not identical with those of the wage earner. The farmer in the United States, like the farmer of other countries, is a conservative. He is a property owner and he has little sympathy for state socialism or anything that approaches it, because he knows government enterprises must be supported by taxation. Gompers was convinced that there could be no permanent alliance between wage earners and farmers.

Advantage will be taken of the death of Gompers by those who want to change the Federation's policies to launch their efforts. There is certain to be something of a struggle and issues may be confused for a time, but the prospects all are that the policies of Samuel Gompers will thrive even more vigorously now that he is dead.

### Coolidge to Call Conference On Mine Safety

In order to reduce the loss of life in the coal mining industry a national conference will be called early next year by President Coolidge. Steps already have been taken by the U. S. Bureau of Mines to arrange a program for the conference, and invitations will be sent out soon after Governors-elect in the coal states have taken office.

The frequency of coal mine explosions with great losses of life, together with the ordinary hazards of the industry, have led to a conclusion on the part of the President and Interior Department officials that the federal government might properly seek the co-operation of the states in promoting greater safety to coal mine workers.

The Governors of all of the principal coal-producing states are to be asked to send representatives, and, as planned, the gathering will include federal and state authorities and representatives of the management and of the workers in the industry.

## Oklahoma Slowly Breaks Grip of Union And Returns to 1917 Scale

After Summer of Trouble 84 per Cent of Output Now Produced by Union Men Paid Basic \$5 a Day — Henryetta Field Alone Pays \$7.50 — Operators Quit Association

Eighty-four per cent of coal now being produced in Oklahoma, it is estimated, is being mined by 28 mines under the 1917 wage scale, representing a substantial reduction from the scale of 1924. Henryetta, alone, of the important coal mining districts of the state, is operating under the 1924 scale, which is a heavy handicap in competition with operators of the McAlester and Wilburton fields.

The movement toward lower wages and the open shop really started last April at the time of the scale conference in Kansas City, when members of the Southwestern Interstate Coal Operators' Association and representatives of the United Mine Workers of Kansas, Arkansas, Oklahoma and Missouri signed a three-year contract on a basis of the high post-war scale. At that time operators declared the scale confiscatory, and those of the Henryetta (Okla.), the Kansas, Missouri and Arkansas fields who signed, since have had open fewer mines than in preceding years.

McAlester and Wilburton were not represented generally at the Kansas City conference. There operators at first refused to accede to the demands of the miners for a three-year extension of the high scale. The mines were idle during the summer until July, when the open shop movement became active. Those operators who then began to clean up in readiness for opening moved cautiously. They employed no brass bands to advertise their intentions. Here and there operation was started on a small scale, opposed, naturally, by union officials, but made possible by individual members of the union, who, after several months of idleness, were in need of employment.

### Conditions Favor Resumption

Here a situation peculiar to the district acted to aid operators resuming production. The district employs few itinerant miners. Many of them own their homes. They preferred to remain where they were at a smaller wage than to seek higher wages in other fields. And when, in the late summer, they perceived they were following a lost cause in holding out for a three-year extension of the 1923 scale, many were ready to accept offers of the 1917 scale.

For several weeks there were sporadic but insignificant clashes between those who had returned to work and those others who continued to refuse to work for less than they had received in 1923. These grew more severe and finally culminated in organized attacks on mines in the Wilburton district, most notable of which were the Kali-Inla raids of July 18 and Sept. 7, in which open shop workers were shot from ambush, and the attack on Rock Island No. 12, Oct. 6.

Oklahoma national guardsmen were sent to the aid of county officials.

Localities in which trouble had occurred were under virtual martial law until last month, while those mines whose operation had brought on the trouble continued to work and others were opened. The number of deserters from the hold-out faction steadily increased until organized opposition melted away. Last week production in the Wilburton and McAlester fields averaged between 5,000 and 6,000 tons a day.

The mines are not operating on written contracts. At each there is a verbal agreement between the company and the miners as individuals that the scale shall be that effective in November, 1917; that disputes shall be referred to an arbitrator selected by the mine foreman for the company and a committee of miners, and that other working conditions shall be the same as those in effect through the remainder of the Southwestern district under the 1924 contract.

The day wage scale under which the mines now are operating is on a basis of \$5; under the 1924 Southwestern contract it would be \$7.50. The pick scale is on a basis of \$1.01 a ton; under the 1924 contract it would be \$1.25 a ton. There is a 14c. differential between the pick scale and the electric chain machine scale for those mines using machines, allowing a loading price of 72c. a ton, and a runners' and helpers' rate of 15c. a ton.

### Many Mines Affected

Among the companies that now are working on this basis are the Rock Island, one mine, No. 12, at Harts-horne; Great Western Coal & Mining Co., two mines, Krebs; Oak Ridge Coal & Mining Co., one mine, Red Oak; Hailey-Ola Coal Co., three mines, Hailey; Milly-Dow Coal Co., one mine, Dow; Pete Pierce Coal Co., one mine, Carbon; Kali-Inla Coal & Mining Co., one mine, Cambria; McAlester-Edwards Coal Co., three mines, which have been operating open shop three years near Pittsburg, Okla.; the Osage Coal & Mining Co., two mines near Harts-horne; Deegnan & McConnell, three mines at Wilburton; two mines at Coal Gate, and five small slope mines near Lutie, about two miles from Wilburton.

This makes a total of 25 mines using the 1917 scale and the number increases with the market. There are about 60 shipping mines in these fields. All those operating under the new arrangement have withdrawn from the operators' association which signed the Jacksonville agreement.

### Miners Want Tax Repealed

Repeal of the anthracite tax will be sought at the coming session of the Pennsylvania Legislature by the anthracite miners, it has been learned at the office of Thomas Kennedy, president of District No. 7, at Hazleton.

## Expect Anthracite Strike to End This Week

Scranton, Pa., Dec. 22.—Officials of District 1, United Mine Workers, expect a break in the strike of 12,000 Pennsylvania and Hillside Coal & Iron Co. mine workers this week.

Rinaldi Cappellini, district president, announced yesterday that he would attend a special meeting of the Underwood Colliery strikers in Olyphant today and take a vote of the men on a proposition to end the strike immediately and allow him to handle the Underwood grievances. He declared that he would meet with all of the other locals affected by the general committee's strike order and submit his request for a poll on the ending of the walkout to the membership of the individual locals.

Members of the investigating committee sent here by John L. Lewis, International president, have left for their homes for the holidays.

Twelve thousand employees of the Lehigh Valley Coal Co. who planned to take a vote this week on the question of joining in a sympathy strike with the 12,000 employees of the Pennsylvania Coal Co., who have been idle three weeks, were warned by district union leaders that any such action would be recognized as a violation of union laws and would be dealt with accordingly.

The District Executive Board in special session at Scranton sent telegrams to the twelve local unions of the Lehigh Valley Coal Co. advising them to live up to their contracts and not to vote for a strike.

## Court Allows Trial by Jury In Labor Disputes

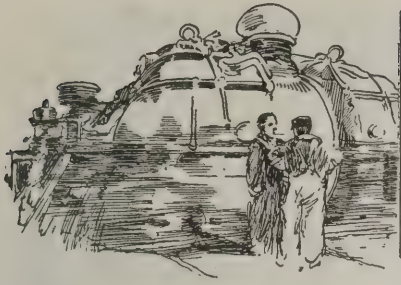

The U. S. District Court for the Western Kentucky division, at Louisville, was reversed Dec. 11 regarding right of jury trial for defendants in labor disputes by the U. S. Circuit Court of Appeals at Cincinnati, which based its judgment on a recent decision of the U. S. Supreme Court. The lower court fined S. C. Nandefor and Letcher Martin, leaders of employees of the Canoe Creek Coal Co. for contempt of court in violating an injunction order restraining employees and United Mine Workers from interfering with the operations of the company in any way.

The men demanded trial by jury, which was refused by the lower court in its interpretation of Sec. 22 of the Clayton Act. The Circuit Court of Appeals, on the previous decision of the Supreme Court, held that this section was no bar to the rights of the men to trial by jury.

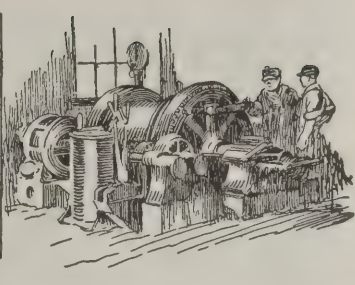

## S. D. Warriner Off Mine Board

Samuel D. Warriner, of Philadelphia, president of the Lehigh Coal & Navigation Co., announced his resignation as a member of the Anthracite Conciliation Board at a meeting Dec. 20 at Hazleton, Pa., of operators whose mines are in District No. 7 of the United Mine Workers. Mr. Warriner said that his resignation was due to pressure of other business. His brother, J. B. Warriner, general manager of the Lehigh Coal & Navigation Co., was elected to succeed him.

## Practical Pointers For Electrical And Mechanical Men

### Slope Switch Controlled By Operator Stationed in Hoist House

Wire Rope Connects Spring-Operated Switch with Hoist—Device Saves Time and Reduces Labor

At the Big Four mine of the Pond Creek-Pocahontas Co., Big Four, W. Va., a simple arrangement for throwing a switch from a distant point was recently applied. This device reduces labor and eliminates delay.

In the background of Fig 1, is the hoist house in which has been installed a new 300-hp. electric hoist. The straight track leading away from the building goes directly down the mine slope which is served by the hoist. Seven-car trips are pulled up through the spring-operated open switch shown in the foreground and are then allowed to run by gravity back on the turnout from this switch and on to the tippie.

The empty-car track is seen on the left of the illustration. From this point the trip of empties is pulled onto the main track and then lowered down the slope. This makes it necessary temporarily to close the switch—shown in the immediate foreground—against the force of the holding spring. Formerly this was done by hand in the ordinary way but now it is performed by the hoist operator, a wire rope being connected to the switch and leading into the hoist house. The rope can be seen lying along the ends of the ties.

The operating lever to which the rope is attached is shown in Fig. 2. This

Fig. 2—Switch-Operating Lever

The short outside lever on this electric hoist is connected by a wire rope to a track switch located at the top of the mine slope.

Fig. 1—Track Switch Operated from Hoist House

When a trip of empties is to be let down the slope, the switch in the immediate foreground is closed by the hoist operator. This is accomplished by pulling on the small wire rope. When the tension on the rope is released the coil spring returns the switch to its normal position.

short lever has been added alongside the regular clutch and brake levers. The lever and quadrant were removed from an old steam hoist. It so happened that few changes were necessary to adapt them to the electrical unit. With the present arrangement when empty trips are to be let down the slope there are no delays nor misunderstandings. The control of the switch is, as it should be, entirely in the hands of the hoist operator.

### Test Device and Transformer Safe and Portable

When making high-voltage tests on armatures and other parts of electrical equipment repaired in the mine shop, certain precautions must be taken when handling the high-voltage cables leading from the source of the voltage to the equipment being tested. This problem is simplified by using a portable transformer, in which case the high-voltage test leads can be made short. When short cables are used they may be heavily insulated, thereby greatly reducing any chance of accident.

Another advantage of having the high-voltage transformer portable is that when so arranged it can be moved to a position close to the work. This brings the transformer tap switch within convenient reach of the operator, making it easy for him to adjust the voltage as desired. The fact that this switch and the entire high-voltage apparatus are in sight, and reach, of the operator adds to his safety and no doubt to his ease of mind.

The illustration shows a portable testing transformer used in the central repair shop of the Hillman Coal and Coke Co., at Brownsville, Pa. Mounted on the same platform with the transformer is an armature-testing device. The height of the magnets is adjusted to various armatures by simply raising or lowering them by hand and inserting a large spike into the proper hole of the telescoping standard. This support is made from two sizes of common pipe one inside the other. The platform carrying the transformer and testing magnets is mounted on three, easy-running, casters.

On the outside of the transformer are three primary leads which, by proper connection to the 220-volt supply line, afford three voltages for each position of the dial switch. The range of voltage is as follows:—for point 1—200, 280 and 450 volts; for point 2—450, 500 and 775 volts; for point 3—550, 750 and 1,375 volts; for point 4—800, 1,100 and 1,650 volts; and for point 5—850, 1,875 and 2,400 volts.

The positions of the switch for obtain-

#### Armatures May Be Tested Safely With This Outfit

The testing device and transformer are mounted together, on three casters. The high-voltage testing leads, insulated with rubber hose, are hanging over the top of the board on which the dial switch is mounted.

ing these voltages are marked on the board beside the dial. High-voltage cable covered by heavy rubber hose is used for test leads. Thomas Booker, foreman of the Brownsville shop, explained that the armature testing equipment has no electrical connection with the transformer. Portable leads from the 220-volt supply line are connected to the magnet when they are used for testing an armature. This outfit, including the magnets was made at the Brownsville shop. The transformer was made up from an ordinary unit which had burned out in service.

#### Found That One Set of Gears Was Better Than Two

Helical gears are now being used on many classes of mine equipment. The double-helical, or herringbone gear has been applied to hoisting equipment for many years, and today it is not uncommon to see helical gears in use on mine locomotives. It is claimed that the helical gear is stronger, operates more smoothly and makes less noise than the plain spur gear. Herringbone gears are considered better than plain helical gears because they neutralize thrusts.

#### Tooth Breakage Eliminated by Use of One Gear Set of Helical Type

Originally this pump had a large, plain spur gear on each of the two outside crank disks, and a pinion on the countershaft. An investigation of gear breakage disclosed that due to imperfect machining or assembling one pair usually did all the work. Consequently, one gear and its pinion were dispensed with and the others replaced by the helical type which, due to the tooth design, has greater strength.

The Pittsburgh Coal Co. has improved its vertical triplex mine pumps by taking advantage of the greater strength of helical gearing. As originally built these pumps had a large spur gear bolted to each outside crank disk. These gears were driven from a countershaft to which were keyed two pinions. The duty on these pumps is rather severe and as a result there were many cases of broken gearing.

Before making this change, A. B. Kiser, electrical engineer for the coal company, made an investigation which proved that usually one gear transmitted all the load, because it is exceedingly difficult to set two pinions on the countershaft so accurately that the teeth of both will bear with equal pressure on their mating gears. Even if the pinions were set on the shaft exactly right, the slightest movement or slippage of either would throw all the load on the other. It was therefore apparent that one gear and pinion set should be dispensed with and the other be replaced by heat-treated gears of the helical type. One of the pumps on which this change had just been made is shown as it appeared when in the company's central shop at Library, Pa. The gear guard was removed so that a photograph might be taken.

#### Improves Lubrication of Motor-Generator Set

When a bearing on a large machine fails it is usually a serious matter. The 700-hp., flywheel, motor-generator set which supplies the 1,100-hp. direct-current motor of the main hoist at mine No. 251, known as Coalwood Shaft, of the Consolidation Coal Co., Coalwood, W. Va., was originally lubricated by ring-oiled bearings. There are five bearings on this motor-generator set, including the one small bearing on the outside end of the direct-connected 40-kw. exciter. A failure of one of the large bearings prompted Alexander Harley, superintendent of the power and mining department of this division, to devise an auxiliary system.

#### Oil Pump Improves Lubricating System of Large Machine

Sight-feed fittings and petcocks for regulating the flow can be seen above the bearing. In the upper right-hand corner of the room is the 40-gal. gravity feed tank.

The new equipment consists of a gravity-feed system by which two small streams of oil flow continually on top of the shaft at each bearing. The overflow from the oil-cellars runs by gravity to a 10-gal. tank which is located in the flywheel pit just below the floor level. From that point the oil is pumped to a 40-gal. tank set on a platform about 6 ft. above the bearings.

It is interesting to note how the gear-type pump is driven from the shaft of the motor-generator set. The pump is mounted on a forged iron bracket attached to the lower half of the outside bearing of the 700-hp. induction motor. The pump pulley—which is not used as a pulley but instead as a coupling—is set parallel to, and within about  $\frac{1}{2}$  in. of the end of the shaft and is driven by three small studs which are screwed into holes tapped in the end of the shaft. These studs extend and fit loosely into holes drilled in the web of the small solid-spoked pulley.

The original ring-oiling system of the motor-generator set was in no way disturbed by the application of the additional equipment. Therefore, if for any reason, such as insufficient oil or pipe stoppage, the new system should fail, the machine will still receive lubrication from the oil cellars which are always kept full of oil. No bearing trouble has been experienced since the pump and gravity method of lubrication has been added.

#### Insulation Resistance Depends On Design of Coil Slots

When measuring the insulation resistance of a motor winding it is important to remember that insulation resistance is directly proportional to the thickness of the insulation and inversely proportional to the area. In view of the fact that different manufacturers use different materials and different thicknesses of insulating materials, it is possible to find quite wide variations between motors and generators of the same voltage and power ratings. This accounts for the fact that one manufacturer may turn out a motor with 5 megohms resistance while another manufacturer makes a motor of the same characteristics which measures 25 megohms.

## Production And the Market

### Coal Markets Mark Time Save for Fitful spurts And Halts With Weather Changes

With the end of the year in sight the usual pre-inventory attitude of hesitancy pervades the coal market—no one, apparently, desires to place any orders that can possibly be deferred until next month. This disposition to hold off has created a condition of over-supply with all the attendant evils of no bills, distress coal and a softening tendency in prices. The weather, of course, is an important factor, and this at last seems in a fair way to come, at least temporarily, to the rescue of the harassed coal man after an almost unprecedented stretch of mild temperature.

One of the most interesting developments of the season in the bituminous coal industry was the announcement last week of a 25 per cent increase in wages by independent operators in the Connellsville region of Pennsylvania, bringing the scale to the peak level of 1920. Special significance attaches to the action of these producers in view of the effect it will have on the miners in adjacent regions who will be less likely now than ever to ask for an abrogation of the Jacksonville agreement, and a lower wage such as will enable the mines to resume active operation. Orders for the blowing in of nearly 2,500 ovens by the Connellsville plants have been given, which would seem to substantiate in striking fashion the reports of steady improvement in the iron and steel trade. The note of confidence in the industrial prospect gains steadily in strength, Judge Gary having joined the prophets of prosperity just ahead.

#### Demand for Hard Coal Lacks Strength

Trade in anthracite on the whole lacks strength, demand being such that supplies are more than sufficient to take care of requirements. Lower temperatures and curtailment of output by labor difficulties have been steadying influences on independent prices, but even they

could not prevent a slight sag in quotations from last week. Chestnut has forged ahead of stove in popular demand, the keenness of the call for the latter being less noticeable, due in part to the breaking down of egg by some producers. Pea continues sluggish and steam sizes move slowly. With the double purpose of taking care of the demand for chestnut and moving pea coal one of the large companies has introduced what it calls "special chestnut," a mixture of two-thirds chestnut and one-third pea, quoted at \$8.30 per gross ton f.o.b. mine.

Coal Age Index of spot prices of bituminous coal advanced one point during the last week, standing on Dec. 22 at 170, the corresponding price for which is \$2.06, compared with 169 and \$2.04 respectively on Dec. 15.

#### Recession in Activity at Hampton Roads

A marked reaction in activity was in evidence at Hampton Roads during the week ended Dec. 18, when dumpings of coal for all accounts totaled 400,188 net tons, compared with 479,099 tons in the preceding week.

Production of bituminous coal registered a further advance during the week ended Dec. 13, when, according to the Geological Survey, the output was 10,723,000 net tons. This was an increase of 111,000 tons, revised figures show, over the previous week's total, and that despite the fact that production was curtailed somewhat in the Central Western States by the miners' election day on Dec. 9. This was the fifth successive week in which production was higher than that for the corresponding week of 1923. Anthracite output during the week ended Dec. 13 was 1,772,000 net tons, compared with 1,814,000 tons in the previous week and 1,947,000 tons in the corresponding week of last year.

#### Estimates of Production

Cal. yr. to date (c).....	17,391,000	9,134,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Is Full of Coal

A severe swoop of cold, running the mercury down far below zero, froze the Midwest region last week. It caught the territory so full of coal that there was no immediate effect upon the market, but even had there been a sudden wild demand for coal it could not have been met at once because of handicapped rail transportation, broken wires and the streets so glazed with ice that retailers' deliveries were slowed down. The cold gave indication of continuing as the days passed, and the first of this week was scheduled to mark a considerable stiffening of domestic markets.

The situation before the cold spell arrived was this: Eastern non-union mines, unable to place their output elsewhere, had dumped low-price coal throughout the Midwest, especially in and around Chicago. A great deal of coal had been shipped on consignment. Illinois and Indiana mine tracks were groaning under "no bills" of lump and egg. Screenings were short and the price was steadily rising, so that southern Illinois best fine coal had touched \$1.90 following a rise to \$1.75@ \$1.80 on the part of central Illinois stuff, which is near the Chicago steam market. Indiana Fourth and Fifth Vein screenings also were passing \$1.75 on their way up.

Domestic prices were sagging badly. Southern Illinois lump was dragging badly at \$3.25 though the circular ran up to \$3.50; central Illinois was in trouble at \$3 and good eastern Kentucky lump was very difficult to move at \$2.25@

\$2.50. Then came the cold. The effect was to stiffen prices, but the permanency of this stiffening depends largely upon the length of the cold spell.

Railroad tonnage from southern Illinois is fairly good considering, although the Illinois Central has shut off for the rest of the year. Mines work from one to four days a week, depending on railroad and other contracts. Cars are plentiful. In the Duquoin field there is little change since last week and conditions are somewhat similar to those in the Carterville district, may be a little worse. Strip mines through all of these districts are getting in good working time on account of the pleasant weather prevailing up to now and are moving their coal at a price.

In the Mt. Olive field there is a little activity on coal going to the Northwest and contracts take up the steam sizes. Mines there are getting one and two days a week with some railroad business. There are no changes in prices. In the Standard field there is gloom. The operators are still selling coal below cost and the miners are not making enough to live on. Screenings are strong at \$1.25 with a tendency to come down with the colder weather.

With St. Louis dealers' yards loaded waiting for cold weather there was a surplus of all kinds of coal on hand and in transit. Domestic was almost at a standstill though it picked up a little with the cold. Country domestic also has been quiet but is a little more active than local. There is a tendency to buy middle grade coals rather than high grade, with very little demand for Standard.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

Index	1924			1923
	Dec. 22	Dec. 15	Dec. 8	Dec. 24
Weighted average price	170	169	171	178
	\$2.06	\$2.04	\$2.07	\$2.16

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

### Kentucky Was Ready to Shut Down

Summery weather before the cold snap caused a slow market that has resulted in a number of mines closing down until after the holidays, although Kentucky is showing a larger number of operating hours and larger production, with a greater percentage of mines running, probably, than any other state in the Union, figuring on a percentage basis, with the possible exception of West Virginia.

Prices are weak all along the line. It was reported that some West Virginia 4-in. lump had been offered at Louisville at \$1.80 a ton. Some Harlan coal was offered to jobbers at anything they could get for it, the understanding being that it was demurrage coal. West Kentucky 6-in. block is selling at \$2@2.25, with some forced sales reported as low as \$1.60@1.75. Eastern Kentucky block coal is \$2.25@2.50 and as high as \$2.75 asked, with some specialty coals probably selling as high as \$3.25, although \$3 appears to be even above the buying top under existing conditions.

Screenings are selling at 80c.@\$1.10 for eastern Kentucky, with some stock reported at 75c. Western Kentucky is quoting \$1@1.15 a ton. Mine run in either field is \$1.35@1.60, with some as high as \$1.75. Lump, egg and nut are generally quoted at \$2 and under, small nut as low as \$1.40, with some good egg and lump quoted slightly over \$2.

### Northwest Docks Are Rushed

Two more ships, loaded and cleared from lower lake ports on Dec. 12, the last day of the insurance privileges, closed the navigation season at Duluth last week. These ships were not expected this year, hence the report last week that navigation had closed. One of the boats, the E. L. Ford, has arrived with a cargo of Pocahontas at the

Inland dock, and the other, the Grammer, arrived Tuesday night. Dock men assert that the docks are busier now than they have ever been.

Despite the movement, anthracite is still a drug on the market. There is still some Pocahontas left because of recent shipments to the port, but it is stated authoritatively that this will all be gone by the middle of January. Prices are firm all around.

The bituminous movement to North Dakota and northern Minnesota is very satisfactory, and more than makes up for the loss of a great part of the Twin City trade, which is still being served from Kentucky all-rail. Industries also are coming into the field and some have put out their year's specifications already. A few contracts have been let. It looks as if the stocks on docks, which are said to be the largest in history for this time of the year, will be fairly cleaned up before the opening of navigation.

At the Twin Cities real winter weather, with the thermometer below zero, has contributed support to the coal market. Its full effect will not be seen at once. Yard stock must be used first. But prices are stiffening since the cold is beginning to shut off the flow of surplus Chicago and St. Louis coal. Screenings have been steadily rising in price.

At Milwaukee there is a better demand for coal at the docks, and the movement with some dealers is increasing. Dealers are looking for a heavier call for fuel after the holidays, when consumers are expected to begin filling their bins for the real winter months. Navigation is now closed for the winter. During last week Milwaukee received two cargoes of anthracite, amounting to 16,100 tons, and a 7,600 ton cargo of bituminous coal. These cargoes make Milwaukee's receipts for the season 821,962 tons of anthracite and 2,594,623 tons of bituminous coal.

### Western Market Is Steady

A little cold weather in the last week and the promise of more has had a strengthening effect on the Southwestern market. Householders who laid in small amounts early in the fall are being compelled to replenish. There still is a small surplus of coarser grades at the mines, but this is beginning to move. Screenings are becoming scarce.

The Colorado market has softened somewhat due to the sudden appearance of warm weather. Steam and nut coals are really a drug on the market at the present time. Prices on steam coal are listless.

In Utah increased activity in metal mining and smelting is stimulating the slack and coke markets somewhat. The Utah territory has experienced very cold weather in sections during the past week or two, and dealers' stocks are very low as a rule. Mines are working a little better than 60 per cent, but not much. The coast business is described as fair; in the Northwest as "getting better"; Idaho and Nevada "not so good," and Utah "fair." Prices remain steady and collections are improving.

### Conditions Mixed in Ohio

Colder weather north and west has served to bolster up a flagging market at Cincinnati with little spurts of activity. Overproduction is shown by hundreds of "no bill" cars on track. Distress coal is proving a drug on the hope of holding up the price of domestic, and added to this has been open price cutting by large producers in West Virginia. Run of mine for both steam and gas purposes holds to its established keel, while slack, after taking a dip, has recovered from the decrease in the make by mines that have already closed for the holidays. The smokeless market proceeds on its way as usual.

Buying at Columbus is largely haphazard, with many users depending on demurrage coal for supplies. As a result there is little strength shown, and prices, outside of screenings, have weakened perceptibly. Ohio domestic coals are extremely weak and production has slumped. In rural sections coal is scarcer with dealers and a fair business is booked in certain sections. Michigan and Indiana points are pretty well congested, however. Retail prices have softened and some dealers are making low quotations in the hope of cleaning up. Manufacturing has not picked up much and most of the larger consumers have fair fuel stocks. There is a growing scarcity of screenings and prices have advanced sharply.

Slack is scarce compared with demand in the Cleveland market and spot prices have stiffened. Inquiries for other steam sizes are negligible despite the fact that industrial plants throughout this section have but a few weeks' coal

reserves on hand. The railroads are fairly well stocked and retail yards also are pretty well filled up since the domestic trade has been more or less quiet due to the mild weather.

### Situation Changes Little at Pittsburgh

At Pittsburgh a slight increase in spot demand has failed to relieve the highly competitive condition existing. Some shading of prices is suspected; they certainly are no stronger at any point. A technical exception is slack, steam being quotable at \$1.10@\$.1.20 against \$1.10 flat a week ago, and gas at \$1.25@\$.1.35, an advance of 10c. This is attributed largely to light shipment of lump. Independent operators in the Connellsville region have returned suddenly to the Frick scale, adding 25 to 35c. to the cost of producing a ton of coal. This will be reflected in byproduct coal but is unlikely to have any direct influence upon steam and gas coal prices. The steel industry is operating at 80 per cent, against 66 per cent in October.

Little improvement is observable in the Buffalo coal trade. The consumer is very finicky and he will seldom pay full price for a car he may happen to know is stranded. The big smelting furnaces, however, are running at a better rate than they were and the lake trade is already preparing for better business next season. It was pretty nearly spoiled this season by poor ore and coal activity. Bituminous stocks are considerably smaller than they were a year ago and are running down right along. The consumer is eager for bargains and will seldom buy unless he can get them.

### Interest Lacking in New England

In New England steam buyers are as scarce as hen's teeth, and only those factors who have rehandling facilities of their own are in position to adhere to their asking prices of a fortnight ago. Shippers who have cargoes on hand at railroad wharves are forced to accept new low levels almost from day to day, and profits have gone by the board.

Accumulations are again the rule at the Virginia terminals. The agencies are therefore once again curtailing shipments to tidewater and at the time insisting upon prices that range from \$4 flat to \$4.25 per gross ton, f.o.b. vessel, even though on car figures at this end will net less than \$4 at Hampton Roads. Neither off-shore nor coastwise is there anything to warrant higher f.o.b. levels than now prevail.

How the trade regards the 1925 outlook is reflected in bids submitted Dec. 15 for New Haven R.R. supply for the coal year 1925-6, as low as \$4.94 having been named alongside Boston for Kanawha coal and \$4.80 for coal from the Fairmont district. Both are coals taking a higher rate to Tidewater than Pocahontas and New River.

All-rail demand is no exception. The tonnage moving is light, and there are few signs of better business ahead.

### Interest Picks Up in Atlantic Markets

Activity at New York was fair during the week. Contract coal moved freely and consumers bought enough to meet current needs, inventory time being blamed for purchases not being heavier. Inquiries on contracts for next year are beginning to arrive and many are about ready to be closed. Railroads are buying good sized tonnages where the prices are right, but there does not seem to be any hurry otherwise. Tidewater coal moved slowly during the week. Receipts are heavy considering conditions, but prices remain steady.

At Philadelphia a little more interest has been shown in the trade recently. The business situation is improving, the trend in textiles continuing the good pace in evidence

since early November. The iron trade, however, shows the most satisfactory improvement, and is buying more coal. The railroads also continue to add to their piles. Gas slack is the only coal that is not equal to the demand. The continued shortage of orders for screened coal holds back the tonnage of fine coal, and prices usually are only quoted from day to day on it.

The Baltimore trade hails the passing of the old year, confident of improvement in respect to both gas and steam fuels. For a number of weeks the demand has been light and even the restricted output in excess of actual demand. This has meant an accumulation at both producing points and at tide, the latter in such cases where coals have been brought through in quantity on other than direct consignment. Increasing export trade to Mediterranean ports has given encouragement to that end of the business.

While there is no active demand in the Birmingham market, some new steam business is being booked, mostly in the open market, with a few contracts being negotiated recently. It is stated that the Mobile Light & Power Co., which has been using fuel oil for some time, will return to coal for power production. General industrial demand is slightly improved.

### Anthracite Trade Lacks Strength

Anthracite demand at New York has been rather weak and there has been more than enough coal to meet requirements. But for reduced output independent coals probably would be begging by this time. As it is quotations for the important coals are lower than last week. Chestnut has displaced stove as the leader in demand in the New York market, but this is partly due to increased peddler and cellar trades. One of the large companies has put on the market what is known as "special chestnut," consisting of a mixture of chestnut and pea. It is quoted at \$8.30 per gross ton f.o.b. mine. The situation with regard to stove has been eased considerably by the breaking down of egg coal by some operators. Pea and the steam sizes move slowly.

The Philadelphia market is not at all strong. Nut continues most in demand but stove is far from being sought after as it was a few weeks ago. There is hardly any demand for egg and all companies are breaking it down to smaller sizes. Steam coals are inclined to be draggy, and there appears to be more than enough to go around.

Domestic consumption at Baltimore has been at a minimum, and as a result dealers, while for the most part cautious not to overstock and tie up their money, are fairly well crowded with supplies and able to handle all possible demands rapidly. Dealers in some cases complain of poor preparation of coal by producers.

Anthracite trade at Buffalo is decidedly slack. The weather has not been cold enough to encourage buying and the prediction of a fierce blizzard in sight, bound this way, does not help matters. The sellers of independent anthracite agree that they are not doing much trade and their prices are not satisfactory. There is so much coke, oil, smokeless coal and natural gas to be had that the anthracite trade is pretty badly cut to pieces.

## Foreign Market And Export News

### British Market Improves in Tone; Price Level Firmer

The Welsh steam coal market has improved in tone and is steadier, though it is not certain whether this is to be taken as a definite all-round improvement or merely the result of overseas buyers seeking to place the balance of this year's requirements and so obtain shipment before the Christmas holidays. For several months buyers have been holding off the Welsh market and have used American and German competition with the view of forcing down Welsh prices. European stocks in consequence have attained a low level, and it is now generally recognized that no further reductions in Welsh prices are forthcoming. Shipments are heavier though still below normal and operators are getting slightly higher prices. No pits have reopened but those that had been working irregularly are now operating more consistently.

The Newcastle market also has im-

proved and inquiry has broadened out, the steam coals collieries having a clear program of work until the Christmas holiday. Gas and coking coals are pretty well booked.

A contract has been placed for 25,000 tons of Durham or Northumberland steams for the Swedish State Railways, shipment to be made from January to April. There are various other smaller contracts, mostly for gas coals, none exceeding about 5,000 tons. It is rumored that an Italian order for 750,000 tons of large coals has been placed at 24s. 6d. to 25s. 6d. f.o.b. Wales. The Dutch Ministry of Marine is asking tenders on 13,000 tons.

Production again advanced slightly, the output of the British collieries in the week ended Dec. 6, a cable to *Coal Age* states, being 5,336,000 tons according to the official reports. This compares with 5,303,000 tons produced in the preceding week.

### No Relief for Dullness in Sight In French Market

Little change is discernible in the French market, house coals being relatively quiet and the industrial coal market dull. Though holidays will help to reduce the output this month, imports from South Wales have been lower this week and French buying of German "free" coal is limited. Canal freight is steady at 25f., Béthune-Paris, and the rolling stock situation is normal.

In the first ten days of December the supply of Ruhr coke totaled 135,125 tons, a daily average of 13,500 tons. Last month's deficiency of supply is being partly covered this month. The price of indemnity coke is unchanged. With the exception of the Aciéries de Longwy, which were not part of the former association, all members of the O.R.C.A. have adopted a new status, which is expected to be signed at an early date.

During the first twenty-nine days of November France and Luxemburg received indemnity deliveries of 202,600 tons of coal, 213,300 tons of coke and 40,900 tons of lignite briquets, a total supply of 456,800 tons and daily average of 15,700 tons.

### Dullness Becomes General at Hampton Roads

Business at Hampton Roads is very dull, due chiefly to unusually warm weather, stopping of lake shipments and the general pre-holiday lull. The market has weakened somewhat, and the outlook for business before Jan. 1 is not bright.

Some foreign movement was recorded, but it was mainly on contracts which were being closed out. Bunker business has been fair, coastwise movement showing a decrease. Inquiries have slumped and large accumulations are piling up at the piers.

Reports from fields serving the port were that practically all coal operations, particularly those in West Virginia and southwest Virginia, would close down Dec. 20 and remain inactive until Jan. 2. Shippers looked forward to the closing of the mines in expectation of that action having a tendency to stimulate the market.

## News Items From Field and Trade

### ALABAMA

According to the annual report just submitted to Governor Brandon by the State Board of Administration, the net earnings of state convicts employed in and around coal mines in Alabama last year were \$621,967.04. State convicts are employed in Flat Top, Belle Ellen, Banner and Aldrich mines, the three former being large operations. The prisoners are worked under the care and supervision of the state.

### IDAHO

The Equitable Coal Co., a Utah corporation, has been denied permission by the Idaho authorities to sell stock in that state. It was held that investors were not sufficiently protected in that an extravagant proportion of the stock is held out for promotion services. It also was held that the security of the company's property, consisting of 1,440 acres of coal land, was not satisfactory. "This application," said the Idaho commissioner, "discloses that the corporation is the holder of a lease of 1,440 acres, a part of which is subject to cancellation at any time by the Secretary of the Interior upon the failure of the lessor to comply with any of five or six conditions."

### ILLINOIS

The 1,400 inhabitants of Glen Carbon, dependent almost entirely on mine No. 2 of the Madison Coal Corporation, are happy. For nine months the mine failed to work a single day. Then without warning a message to resume operations came and on Dec. 15 the big whistle sounded, calling the miners to work. Thirty men were lowered into the shaft to clean up fallen debris and on Dec. 16 the machine runners started actual mining.

Harry Tanner and Charles Law, of Pana, have sold the Litchfield coal mine, at Litchfield, to John Puckett, of that city, for \$60,000. Temple McDonald, of Hillsboro, has been named manager and will reopen the mine.

Reports from the office of C. J. Nelson, general agent of the Chicago, Burlington & Quincy R.R. at Herrin state that October was the largest month in coal traffic this year. In October the road handled 1,150,040 tons of coal in a total of 23,047 cars.

Two new railroads will be constructed, if they are granted permission, in Franklin County, centering around Benton, the country seat. The Herrin-Benton Ry., which would operate from Herrin to Benton, and the Benton Northwestern Ry., which would operate

from Benton to McLeansboro, have both filed petitions with the Illinois Commerce Commission. They both will be operated by steam and the former will carry all classes of passengers, freight, etc., while the latter will handle freight traffic only.

William Cowell, mine manager of Bell & Zoller mine No. 2 at Zeigler, has resigned effective at once to accept a similar position with the Chicago, Wilmington & Franklin Coal Co.'s Orient No. 2 mine, at West Frankfort. Henry Taak, of Centralia, has been appointed to fill his vacancy in Zeigler.

The Gulf Mine at Sparta failed to pay off its regular bi-weekly payroll Nov. 30 and as a result the property is idle. According to reports the company was able to pay only about 25 per cent to the 250 men employed.

### INDIANA

Cairy Littlejohn, state mine inspector for Indiana, is in a serious condition at the Methodist Hospital, Indianapolis, following an operation for intestinal trouble nine days ago. His condition has become serious during the past few days.

Initiation fees in District No. 8, United Mine Workers, comprising virtually all the block coal field of Indiana, will be \$20 instead of \$10 after Jan. 1. This was decided at the recent convention held in Brazil. A rule also was passed by which persons who go to work in non-union mines or shops and afterward want to regain their membership in the union shall pay, in addition to the regular initiation fee, a fine of \$50, the fine to go to the local union.

### KANSAS

A class in mining has been organized at Arma with seventeen members, under the instruction of Obadiah Dray and the supervision of Prof. J. A. Yates, of the Kansas State Teachers College, to study mine gases, mine timbering, safety lamps and other subjects, a knowledge of which is necessary to pass the state mine examination.

The assessment of \$1 a week levied on members of District 14 (Kansas), United Mine Workers, for each week a member worked, for the relief of the unemployed, has been discontinued. On Dec. 1 the special fund showed a surplus of \$15,000 from the money paid in since June 1. At the same time that members of the district were notified that the one special assessment had been discontinued they also were informed that another assessment of \$1

a week for December and January had been levied for reimbursement of the general fund.

### KENTUCKY

The West Kentucky Coal Bureau's annual meeting and election will be held at Louisville Jan. 13. W. G. Duncan, of Greenville, is president.

The slow coal market at the present time and low prices in effect have resulted in operators of striking mines in western Kentucky losing interest in trying to get such mines running for the time being. So far there hasn't been much progress made in the Central City section, where the strike is now nearly eight months old.

A report from Barbourville is to the effect that core drilling with six out-fits has started on Henry Ford coal properties in eastern Kentucky, which were purchased from the Peabody Coal Co., in Clay and Perry County. Much of the acreage is off railroads and will have to be proved before opening. A good deal of it is alleged to contain small seam coal. However, there are 80,000 acres to be proved and some of this represents mighty fine coal land.

A. S. Bennett, secretary of the Workmen's Compensation Board, reporting to Governor Fields, on the board's activities for the year ending June 30, 1924, showed a total of 11,573 coal mine accidents out of a total of 28,133 accidents recorded. There were 27,569 males injured and 564 females. There were 15,447 agreements approved, involving payments of compensation amounting to \$1,459,637.62, and to injured employees or dependents of deceased employees \$303,638.64 was awarded.

### MASSACHUSETTS

The Massachusetts Special Commission on the Necessaries of Life, following an investigation of coal deposits in southeastern Massachusetts, has recommended to the State Legislature that an appropriation of \$50,000 be made to pay for an exhaustive investigation on the part of a special state commission into the quality as well as the commercial quantity of such coal available.

### MONTANA

Montana's coal output has slumped during the fiscal year 1924, along with that of most other states. The report of Inspector George N. Griffin, just out, shows that 3,035 men were employed, producing 2,988,799 tons. In Montana's banner year—1920—4,108 men produced 3,381,840 tons.

## NEW YORK

The first meeting of creditors of the Lake Erie Coal Co., Buffalo, was held Dec. 15 in bankruptcy court, when Rumsey Wheeler was appointed trustee and Frank Fitzpatrick attorney. No schedule was presented.

## OHIO

J. W. Richardson, general manager of the Splashdam Coal Co., of Splashdam, Va., was a recent visitor to Cincinnati equipment people concerning proposed betterments to the plant.

The Central West Coal & Lumber Co., of Columbus, will soon start the rebuilding of the tippie and power plant at Mine No. 24, near Jacksonville, Athens County, on the T. & O. C. R.R. which was destroyed by an explosion several weeks ago. Machinery for a shaker screen, picking table and loading boom will be ordered soon and work of construction will be pushed. Nothing definite has been discovered as to the culprits causing the explosion. Mine No. 68, nearby which was slightly damaged at the same time, has been in operation almost continuously since the disaster. The loss was in the neighborhood of \$50,000 and that amount will be expended on the new plant. It is planned to use loading machines in the mine when reopened as four such machines are now being used in Mine No. 68.

Federal court has approved an order for the sale of the three Ohio mines of the Maynard Coal Co., located in the Pomeroy field, at auction at Pomeroy, Meigs County, Jan. 7. At the same time an order was issued for the sale of the three mines in the Hazard field, Kentucky, at Hazard, Perry County, Jan. 10. In each field there are three mines, all well equipped. The capacity of the three Kentucky mines is about 3,000 tons daily and that of the three Ohio mines about 1,500 tons daily. William S. Haman and Frank L. Stein, of Columbus, are the receivers.

Following the return of the Hazard Jellico Coal Co., which was operated by Jewett, Bigelow & Brooks prior to the bankruptcy proceedings, to the Harvey

Coal Co., its original owners and from whom it was purchased on a payment plan, a new corporation has been formed with C. H. Harvey, president; F. L. Fisher, vice president, and Fritz Staub, secretary and treasurer. This will be known as the Harvey Coal Corporation and it is now in full charge of the operations at Harvettown, Ky.

Suit has been brought by the Essex Coal Co., of Columbus, against the Northern Fuel Co., of Toledo, asking for the appointment of a receiver for the Toledo company. The claim is made that there is an unpaid judgment.

## PENNSYLVANIA

The John Mitchell Mutual Life Insurance Co. has elected officers and will start the issuance of policies on Jan. 1. It is a United Mine Workers organization, although independently controlled. J. J. Helferty, of Hazleton, has been elected president. The first policy will go to Chris Golden, of Shamokin, president of District 9, United Mine Workers, whose efforts in behalf of the concern have figured prominently in its successful organization.

The Lehigh Valley Coal Co. has declared an initial dividend of \$1.25, payable Jan. 31 to certificate holders of record Jan. 15.

Michele Bassi and Tony Pezzi, alleged bandits who shot and killed an express company guard during the holdup of a train carrying the payroll of the Ebensburg Coal Co. at Raxis, near Colver, on Oct. 11, and who got away with more than \$33,000, have been convicted of murder in the first degree in the Cambria County courts. A third member of the gang, Pete Antonucci, will be tried in January. The men were stopping at a hotel in Terre Haute, Ind., when arrested. The automobile used in connection with the holdup proved to be the one used in the holdup of the East End Coal Co. payroll of \$70,000 on July 30 in Lackawanna County. The verdict carries with it the death penalty under the Pennsylvania laws.

A deal has just been closed whereby Dr. John P. Hagg, of Williamsport,

becomes the owner of a piece of coal land in Karthus township, Clearfield County. Both the coal and surface rights are included in the deal. There are three veins of coal on the tract, some 6 ft. thick. It is estimated that the territory purchased will produce several million tons of coal. The land adjoins the holdings of the Snowshoe Independent Coal Co., of which Dr. Hagg is president. A railroad siding has just been completed to the company's holdings.

## TENNESSEE

The J. G. White Corporation is understood to have effected a combination of several large coal and iron ore properties, blast furnaces and similar plants in the Chattanooga district. The total involved is reported to be between \$8,000,000 and \$10,000,000. Among the companies said to be involved in the merger are the Roane Iron Co., the Tennessee Consolidated Coal Corporation, the Bon Air Coal Mines, the Chattanooga Coke & Gas Co. and the Chattanooga Iron Co.

## UTAH

The Blazon Coal Co., of Salt Lake City, a mining concern, has been granted a permit to offer for sale 94,801 shares at \$1 per share.

The Independent Coal & Coke Co. has filed suit against the Receiver of the Denver & Rio Grande Western R.R. for \$2,254, alleged to be due for losses sustained through fire caused by the railroad's negligence. It is claimed that the coal company lost the amount mentioned in lumber and wooden pipe as a result of a fire caused by sparks from the engines of the railroad.

Zeth Thomas, superintendent at Castlegate for the Utah Fuel Co., has resigned and gone to St. George, in southern Utah, where he will make his home for the winter. He will be succeeded by Mine Supt. T. A. Stroup, of the Clear Creek group of mines. Mr. Stroup will be succeeded by J. W. Littlejohn, chief inspector of the company's property at Sunnyside, and a brother of General Supt. William Littlejohn.

## VIRGINIA

Ira Cochran, commissioner of the American Wholesale Coal Association, Washington, was the guest of the Hampton Roads Coal Association and the Norfolk Wholesale Coal Association last week. He addressed the association on the subject of the operations of his association, and inspected the coal terminals.

## WEST VIRGINIA

The American Coal Co. of Alleghany, for the ten months ended Oct. 31, 1924, reports net earnings of \$208,117 after depreciation but before taxes, which compares with net earnings for the year ended Dec. 31, 1923, of \$915,000.

The Goodwill Coal & Coke Co., operating in Mercer County, in the Pocahontas district, has virtually completed

Courtesy Bertha-Consumers Co.

## Playground at Rachel Mine

If fresh air and fun make healthy and happy children, then the younger generation in the vicinity of Downs, W. Va., where this operation of the Bertha-Consumers Co. is located, need no commiseration, for their wants have been well provided for by the coal company.

extensive repairs and alterations to its tippie. The mine of the company is one of the oldest in the Pocahontas section. About 600 men were idle for two weeks while the changes were being made.

The supply tippie of the Elk Lick Coal Co., near Richwood, recently was destroyed by fire. The Elk Lick mine is owned by the Cherry River Boom & Lumber Co.

Preparations are being made by A. J. Thompson and associates, of Titusville, Pa., to install a plant near Flint, on the Durbin branch of the Western Maryland Ry. Tests have indicated the existence of the Sewell seam with a thickness of about 42 in., over an area of from 600 to 800 acres. The coal found by tests shows a little better analysis than the New River coal found in Rich Mountain. Between \$25,000 and \$30,000 will be expended in preliminary development work under the direction of Oren Kelly.

Fire, believed to have been of incendiary origin, recently entirely destroyed the Recreation Hall at the Grant Town operation of the New England Fuel & Transportation Co. The building together with its contents was valued at \$20,000. It was impossible to save the building or any of its contents and a force of volunteer firemen devoted their efforts toward saving adjoining buildings. The building contained bowling alleys, pool tables, a moving picture theatre, club rooms and all the necessities for a community center. The fire followed shortly on the heels of a rumor that the recreation hall was to be used as a rooming house.

The Marshall Coal Co., operating at Mt. Clare, in Harrison County, sustained a loss of about \$1,000 when six mine dwellings were destroyed by fire, the blaze starting as the result of a defective flue in dwelling No. 3.

The Bethlehem Mines Corporation, a subsidiary of the Bethlehem Steel Corporation, resumed operations Dec. 15 on an open shop basis at its Dakota mine, in Marion County one of the largest mines in northern West Virginia. The mine had been closed down since April 1, when the company declined to sign the Jacksonville agreement. The Dakota mine has a capacity of from 40 to 50 cars a day. Although the mines of the Bethlehem company on the Morgantown & Kingwood have been operated open shop for some time, the Dakota and Barrackville mines acquired from the Jamison Coal & Coke Co. were operated as union mines up until April 1.

## WISCONSIN

A court order has set Jan. 5 as the date at which the Reeves coal dock at Superior, will be sold. The property of the company in the Twin Cities also will be sold. It is rumored that the president of the company will endeavor to get together enough capital to buy the Superior dock, in accordance with former plans announced some months ago. It is definitely stated that Henry Ford is not interested in the defunct company.

## CANADA

Carbon, Alta., on the Canadian Pacific Ry. in the southern part of the province, promises to develop into a mining town of considerable importance within the next few months. The Carbon Coal Co. has obtained extensive concessions and, according to a statement of H. Ransford, South Wales capital has been interested in the venture and work will be begun on a large scale immediately negotiations have been completed.

A readjustment of duties on United States coal so as to afford adequate protection to the coal industry of the Maritime Provinces and a careful investigation of the tariff on coal and semi-finished steel products was urged by a delegation headed by Premier Armstrong of Nova Scotia which waited upon the Federal Government at Ottawa last week.

T. J. Brown, Deputy Minister of Mines of Nova Scotia, has notified Malcolm Blue, general manager of the Nova Scotia Steel & Coal Co. that the company cannot continue to have policemen and watchmen tend the fans in the Albion mine near Stellarton. They must be replaced by members of the United Mine Workers according to the decision of Mr. Brown, whose attention was called to the situation by Thomas Scott, district board member of the miners' union for the Pictou territory.

Norman Harvey, acting on behalf of the Vancouver Harbor Commission, has just completed a survey of coal deposits in Alberta province in connection with a report to be issued in the near future by that body. The commission intends to classify the coals of Alberta and British Columbia under their respective heads and review the feasibility of marketing certain kinds through Vancouver port.

The Northern Alberta branch of the Canadian Institute of Mining and Metallurgy has elected the following officers for the ensuing year: Norman Fraser, chairman; David Jones, vice-chairman; H. M. Roscoe, secretary; L. C. Stevens, treasurer, and an executive committee composed of K. Campbell, A. C. Dunn, T. Hollies, J. W. Cashmas and J. A. H. Church.

Ninety days of work on a site alongside the Alberta Coal Branch of the Canadian National Ry. has resulted in the birth of a new mining town to be called Bryan, Alta., from which coal is already being shipped. Since the middle of September a tippie and power house have been built, nearly a mile of railway, with three switches constructed and a 325 ft. shaft sunk to the coal. The mine has an anticipated output of 1,000 tons a day. Officials in charge of the new mine are as follows: James H. Bryan, president; Charles Robertson, vice-president; John R. Macdonald, general manager and superintendent; Colin McGillivray, master mechanic, and Fred McKenzie, accountant.

Owing largely to the strike last summer the year's coal production in Alberta will not equal that of the previous year. Figures recently issued show a

total output of 6,866,923 tons during 1923 and a total of 3,589,884 up to the end of October of the present year.

"No evidence whatever was adduced at the inquiry to support the theory of a combine among either Winnipeg coal dealers or Alberta operators," declared Howard Stutchbury, Trade Commissioner for Alberta, on his return from Winnipeg, where he spent two weeks attending the government investigation into alleged conspiracies to keep up the price of coal in the prairie city. The inquiry was begun at the instigation of A. B. Hudson, a Winnipeg coal dealer who professed knowledge of a combine in that city, which he thought was preventing him from buying Alberta coal as he wished.

## New Companies

**The Canyon Coal & Lumber Co.** has been incorporated in Salt Lake City, Utah, by H. E. Havenor, as president; Chas. Kelby, as vice-president, and Alta Snyder, secretary-treasurer.

**The Trumbull-Warner Coal Co.**, Cleveland, Ohio has been incorporated with a capital of \$100,000 to mine coal and deal in coal and coke. Incorporators are Norman A. Emery, Charles F. Ohl, T. Lamar Jackson, Donald J. Lynn and C. Kenneth Clark.

**The Storm King Fuel Co.**, Hazard, Ky.; capital \$25,000, has been chartered by William F. Mandt, Lewis E. Harvie, W. W. Reeves and P. T. Wheeler.

**The Green Coal Co.** has been formed to operate at Madison, in the Boone County field of West Virginia. This company is capitalized at \$100,000. Principally interested in the new concern are: E. J. Goodrich, D. W. Hill, H. D. Battle, H. B. Stubbs and D. C. Howard, all of Charleston.

**Canadian Amalgam Fuel Co., Ltd.**, of Windsor, Ont., has been incorporated with a capital of \$40,000, to manufacture and deal in fuel. Robert McDonald, Fred A. Brandt and S. G. Bawden are provisional directors.

## Publications Received

**Miners' Wages and the Cost of Coal**, by Isador Lubin. Pp. 320; 5½x8 in. Price, \$2.50. An inquiry into the wage system in the bituminous-coal industry and its effects on coal costs and coal conservation. The book analyzes the peculiar wage system that has been developed in the bituminous field and shows how this system has affected the earnings of the miners, the cost of producing coal and the exploitation of our coal resources. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

**Mechanical Engineers' Handbook**—New second edition, by Lionel S. Marks. Pp. 2,000; 4½x7 in.; illustrated. Price \$6. A thorough revision of this handbook. All the material has been brought up to date and much new material included. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

**Annual Report of the Mines Branch of the Province of Alberta, Can., for 1923.** Pp. 339; 6x9 in.; tables.

**Flame Safety Lamps**, by J. W. Paul, L. C. Illsley and E. J. Gleim, Bureau of Mines, Washington, D. C. Bulletin 227. Pp. 212; illustrated. Price, 50c. Gives detailed account of development of present safety lamps from those of Davy and Stephenson; discusses lamp-testing stations and tests made by various governments and by the U. S. Bureau of Mines; also describes devices and methods for testing for methane in mine air.

**Arc Welding Handbook**, by C. L. Holslag. Pp. 243; pocket size; illustrated. Price \$2.00. McGraw-Hill Book Co., 370 Seventh Ave., New York City. Complete working manual for welding operators and those who supervise welding jobs.

## Association Activities

The fifteenth annual convention of the **Winding Gulf Operators' Association** was held at the Hotel Washington, Beckley, W. Va., on Tuesday, Dec. 16. Routine business in connection with trade conditions, tonnage, production and the market situation were given special attention. The officers elected for the ensuing year are: E. E. White, of Glen White, president; P. M. Snyder, of Mount Hope, vice-president; George Wolfe, of Beckley, secretary, and A. W. Laing, of McAlpin, treasurer. W. A. Richards was made a member of the executive committee in place of W. A. Ruby, resigned. Among those attending the meeting were: G. P. Caperton, of Charleston; F. M. Lee, of Alpoca; W. A. Richards, of Ashland; W. B. Beale, of Fireco; L. Epperly, of Winding Gulf; C. H. Mead, of Beckley; T. H. Wickham, of Beckley; Fred G. Wood, of Amigo.

## Trade Literature

The Ohio Electric & Controller Co., Cleveland, Ohio, recently issued Bulletin 204, describing the **Ohio Fractional Size A.C. and D.C. Motors**, 12 pp., and the **Ohio Motor Application Bulletin**, 12 pp. Both bulletins are 6x9 in. and illustrated.

**Footo IXL Speed Reducers.** Footo Bros. Gear & Machine Co., Chicago, Ill. Catalog No. 24. Pp. 14; 8x11 in.; illustrated. Describes the construction and use of reducers to reduce the speed of electric motors.

**Westinghouse Fittings for Pipe Structures.** Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. Circular 1676. Pp. 35; 8x11 in.; illustrated. Describes interchangeable pipe fittings for structural work, giving their application to erection of outdoor substations, switching equipment, switchboard frames, etc. An adjustable insert for fastening machinery or other equipment to concrete floors, walls or ceilings is also illustrated and described.

The Westinghouse Electric & Mfg. Co. recently issued a 16-page booklet, 4x7 in., entitled **Westinghouse Precision Instruments**, devoted to the construction, operation and performance of precision voltmeters, ammeters and wattmeters. The booklet is known as Folder No. 4603.

Allen-Bradley Co., Milwaukee, Wis., recently issued the following: Bulletin 600, alternating-current resistance starters. Bulletin 640, type H-1852, semi-automatic resistance starter. Bulletin 740, type J-3052, automatic resistance starter. Bulletin 720, type J-1552, across-the-line starting switch.

**The Economy of Better Lubrication.** McCord Radiator & Mfg. Co., Detroit, Mich. Pp. 22; 8x11 in.; illustrated. Descriptive of the company's Class B lubricator, adapted to small steam engines, oil engines, gasoline engines, air compressors, steam pumps and auxiliaries. Over-all dimensions and price lists are included. This company has also issued Class BA catalog, describing the lubrication of steam shovels, cranes, dredges, hoisting engines and coal-and ore-handling apparatus.

**Coal and Ash Handling Machinery.** The Jeffrey Mfg. Co., Columbus, Ohio. Catalog No. 385. Pp. 212; 8x11 in.; illustrated. This book is composed of thirteen sections. No. 1 is devoted to pivoted bucket carriers. No. 2 to V-bucket conveyor. No. 3, bucket elevators; No. 4, power-house weigh laries; No. 5, track hoppers, plate feeders and bin valves; No. 6, scraper conveyors; No. 7, belt conveyors; No. 8, Steel apron conveyors; No. 9, pan and spiral conveyors; No. 10, skip hoists; No. 11, crushers; No. 12, coal-storage equipment; No. 13 mechanical draft fans. Typical layouts giving general dimensions accompany the tables of specifications for various equipments.

**Universal Conveyors.** Universal Conveyor Co., South Bend, Ind. Catalog C. Pp. 23; 8x11 in.; illustrated. Monorail and cableway conveyors as a solution of the dealers' coal-handling problems are described.

**Marion Model 350.** Marion Steam Shovel Co., Marion, Ohio. Bulletin 314. Pp. 35; 8x11 in., illustrated. The Model 350 shovel and Model 360 dragline, equipped for either steam or electricity, are fully described. Among the latest developments for the new

Marion is the patented method of equalizing and leveling by hydraulic jacks.

Roberts & Schaefer Co., Chicago, Ill., recently issued bulletin No. 59, illustrating and describing **Marcus coal tipples**. The bulletin contains 6 pp. and measures 8x11 in.

**Sullivan Air Lift Pumping Systems.** Sullivan Machinery Co., Chicago, Ill. Bulletin 71-H. Pp. 47; 6x9 in.; illustrated. The different installations in which these systems are employed are described.

**Interlocking Safety Switch and Plug.** Crouse-Hinds Co., Syracuse, N. Y. Fourteen-page folder illustrating the use of safety switches and plugs with portable electrical appliances.

**Arcwall Coal Cutter.** The Jeffrey Mfg. Co., Columbus, Ohio. Bulletin No. 406, Pp. 8; 7½ x 10½ in. illustrated. Describes the principal advantages of the arcwall coal cutter and its methods of operating.

**Northern West Virginia Coal Operators' Association.** Annual meeting, Feb. 10, Fairmont, W. Va. Executive vice-president, George S. Brackett, Fairmont, W. Va.

**American Institute of Mining and Metallurgical Engineers.** Annual meeting, Feb. 16-19, 1925, 29 West 39th St., New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**New England Coal Dealers' Association.** Annual meeting, March 25-26, Springfield Auditorium, Springfield, Mass. Secretary, C. R. Elder, 141 Milk St., Boston, Mass.

## New Equipment

### Electric Pyrometers Record Clear Indications

A complete line of indicating and recording pyrometers, together with the usual thermocouple accessories, was recently placed on the market by the Republic Flow Meters Co., of Chicago, Ill.

The clock of the pyrometer has a complete time element with the usual escapement and its own main spring. It performs no other function than to

Wall-Type Indicating Pyrometer

A long scale is provided on the meter so that indications are clearly visible. Outside adjustments are made on a moisture-proof twelve-point rotary switch.

release operating energy periodically through the second or power escapement. No power passes through the timing escapement, and as a consequence the timing is not influenced by the quantity of reserve power that remains in the springs. The clock is an excellent time keeper.

In the recording type pyrometer two independent charts are used. With two separate sheets of paper, it is possible to have any combination of scale ranges desired. Six-inch charts are used on the duplex recording pyrometer. The actual scale range is 5½ in.

A tear groove below the driving drum permits extraction of the record instantly without waste of chart paper. A clutch on each driving drum enables one to operate either or both charts at will. The charts last 1,200 hours.

A carbon ribbon is automatically advanced across the face of the chart, and the instrument pointer moves freely between a depressor bar and the back of this ribbon. The pointer deflects in proportion to the temperature at the hot junction of the thermocouple and there is no frictional resistance at

the pointer. Just before the depressor bars come down, the carbon ribbon moves forward, covering the knife edge which runs the width of the charts and is located directly beneath the depressors.

When the carbon has advanced to cover the knife edge, the depressors drop, and a dot is made on the face of the chart. The depressors then rise, the carbon drops back, and the dot that has just been made is visible. In some instruments visibility is attained by having the carbon marking band on the under side of the chart, but this is not as satisfactory. All the charts used in these pyrometers have 20 deg. F. markings at each division. This is true even with the 3,000 deg. F. charts.

All the parts in the recording pyrometer are mounted on a swinging bracket. Every detail is visible and accessible. The bracket also forms a cover for the electric system which is attached to the back of the bracket. Two screws hold the bracket closed and the electric system is thereby thoroughly protected.

Fifty ohms' resistance is taken from the fixed resistor and placed in a variable rheostat having a scale of 25-0-25 ohms. These instruments are accurately calibrated for the external circuits stipulated, but if at any future time it is necessary to change the length of the extension leads, instantaneous and accurate adjustment can be made within the instrument.

A small toggle switch, which is plainly marked "on and off," is built into the instrument, which, when closed, short-circuits the magnetic field and damps the movement of the pointer when in transit. The meters have high resistance which assures accurate reading.

### Compressor Has Improved Type Governors

A new type multi-stage, centrifugal compressor, designed to supplement the line of single-stage machines recently developed, and supplied with improved control devices, is now being marketed by the General Electric Co. These compressors have been especially developed for furnishing various volumes at higher pressures than ordinarily obtained with single-stage machines. Compressors of this type are particularly suitable for pneumatic materials, handling systems, the agitation of liquids and drill machines.

The main line of compressors covers water-cooled machines designed to deliver volumes of from 3,000 to 60,000 cu.ft. per minute, at pressures up to 30 lb. or more. Two types of miniature, self-cooled machines, to deliver from 250 to 1,400 cu.ft. per minute, at pressures of from 2 to 6 lb., have been included in the group. All types are either motor or turbine driven.

Among the advantages claimed for the new compressors are higher efficiencies, simpler and stronger construction, thus minimizing mechanical difficulties. The large cooling capacity is expected to bring about greater efficiency, the conversion passages having been improved and the interstage passages simplified. Each complete unit has four bearings with an automatically lubricated flexible coupling. These

### Compressor Improved

This well-balanced compressor unit can deliver 3,500 cu.ft. of air per minute at a pressure of 17 lb. It is suitable for air hammer drills and is equipped with improved type pressure governors.

bearings are supported by the foundation or base under the machine. In addition to these changes, all the various governing devices for these machines have been improved, including constant-volume governors, constant-suction governors, constant-pressure governors, etc.

### Compact Ribbon Resistor

A ribbon-type resistor, wound on edge, has recently been developed by the Monitor Controller Co., Baltimore, Md. It is intended for service where cast-iron grids would otherwise be employed.

The resistor unit consists of a high-resistant alloy ribbon wound on edge in helical form and mounted on a steel-reinforced porcelain support which passes through the entire length of the unit and also supports and separates each convolution at two diametrically opposite points. This method of construction relieves the resistor ribbon from mechanical strain and permits thorough ventilation. The ribbon can

Fig. 1—Units Are Compact

Bank of four resistor units connected in series and stood on edge with feet turned outwards to show details of construction. There are only three joints in the whole bank, these being made by bridging clamps at the ends of the unit.

operate at any temperature up to red heat without sagging or in any way injuring the resistor as a whole.

By means of terminals and taps a unit may be connected into a circuit or interconnected with other units. Two simple forms of clamps provide all these facilities. One is a bridging clamp which makes solid mechanical connection between two adjacent units as shown in Fig. 3, and which serves as a terminal when the units are connected in parallel and also as an end tap, if desired, when the units are connected in series. The other may be used for either of two purposes—as a terminal clamp or as shown in Fig. 2. The taps may be placed at any desired point along the resistor and may be changed at will.

As the clamps may be used to join ribbons of different sections together at any point, tapered resistors of almost perfect design can easily be made.

The resistors are made in standard units and mounted in frames so that they can be applied in a manner similar

Fig. 2—How Taps Are Made

Clamp used for taking off tap. Same clamp is also used for effecting terminal connections.

to cast-iron grids. The standard section will contain either four or six units mounted horizontally and connected either in series or in parallel. Any number of these sections may be mounted one on top of another. It makes practically no difference whether the resistor as a whole is mounted with the units in a vertical or horizontal position. There are no joints in a resistor section except at the terminals. The ordinary cast-iron section has approximately fifty joints in addition to those at its terminals.

The porcelain used in the resistor being supported by steel is practically unbreakable.

Fig. 3—Joining Sections

This type clamp is used for connecting adjacent units in parallel or series. It serves as terminal when units are in parallel, but also may be used for taking off intermediate taps whether units are in parallel or in series.

CARS mounted on Timken Tapered Roller Bearings are strangers to the repair shop. There is never a long string of cars on the repair siding—when a peak day finds you needing every car you can lay your hands on.

As a result, on Timken-equipped cars, you haul a greater tonnage with the same number of cars, or the same tonnage on fewer cars.

The booklet "Timken Bearings and Coal" gives all the details.

*An Exide-Ironclad Battery equipped locomotive in Kehley's Run Colliery, a subsidiary of Madeira, Hill & Co.*

## At Harleigh-Brookwood Coal Co., Shenandoah, Pa.

Three battery locomotives are operated at Kehley's Run Colliery of the Harleigh-Brookwood Coal Company, a subsidiary of Madeira, Hill & Company. These three are equipped with Exide-Ironclad Batteries, 48 cells MV-25.

The three motors are worked hard, as they are used in both gathering and haulage service. They handle about ninety cars a day each. The cars are big ones, as you will see from the photograph, holding five tons of coal.

Despite the way the batteries are pushed, they are giving splendid service, and repairs have been few. At hundreds of mines throughout the country, Exide-Ironclad Batteries are hauling the coal smoothly, speedily and economically. Those who use them *know* the Exide-Ironclad to be a powerful, rugged and dependable battery.

## We Wish You A Merry Christmas

This day of all the year is full of good cheer and gratefulness, so chockful of happiness that we look forward to it as to an oasis in a desert, where we can take our fill of water from the well and dates from the lofty trees to sustain us through another year's journey.

But there should be no deserts. They are largely of our own making. The song of life should run along steadily year in and year out, only with a deeper, fuller note at Christmas.

Men arrive at their goals as much by being as by planning. Inspiration to our friends and associates to help and serve us comes not so much by the depth of our thought to please as by the cheerfulness and friendliness of our character. If we put the briskness and freshness of Christmas day into our daily lives the seven devils of suspicion, dislike, fear, resentment, ungratefulness, anxiety and mental inertia will be driven out.

He who carries good cheer into his life has not only a good digestion for his food but a wholesome solution for his problems. He who is uninfluenced by imaginary wrongs and ills and unhampered by a gripful of unpleasant memories finds that despite many a discordant note the song of life is attuned always to his.

O-B Renewable Bronze Cam Tips are made with 6-inch approach lips and with 2½-inch approach lips. Where space permits the longer lips are recommended for easier wheel approach.

**1** The tip is inserted, up-side-down, under the hooks cast on the frog body.

**2** It is raised up, over and down onto the wire. The cam end forces wire down into groove.

**3** The lips are clinched around the wire, the whole job on one tip taking about 40 seconds. No nuts or bolts required.

O-B Renewable Cam Tips make O-B Trolley Frogs so easy to put up that they are correctly put up.

Try a Type D or a DM Frog at a heavy traffic point.

O-B Type DM Frog

2½- or 6-inch Cam Tips are interchangeable on all Frogs.

These two frogs are popular ones for mines. The DM is good for short radius curves as it is short enough to allow quick turnouts. The D makes a smoother passage for the trolley wheel and is recommended where track curve radius will permit.

*Jeffrey Arcwall Bottom Cutter cutting along bottom*

## *Cuts Anywhere Between Roof and Bottom*

The Jeffrey 29-C Arcwall Coal Cutter can be adapted for cutting any place between bottom and roof; in the coal, or in shale bands or dirt. Adjustable while in operation to an irregular binder.

No time is wasted in loading or unloading as machine is operated on truck. Averages 20 to 30 working places cut in an 8-hour shift.

Produces more

lump as light charges of powder may be used. Insures cleaner and better coal at less cost.

The Arcwall Bottom Cutter permits undercutting on the bottom without interfering with track, leaving no wedge shaped portion and entirely eliminating expense of taking up bottom after a place is cut.

## COAL MINE EQUIPMENT

# WEBSTER COAL TIPPLE EQUIPMENT

*"Includes Everything for the Handling - Preparation and Loading of Coal"*

The Webster name is conspicuous in the coal mining field due to what it has accomplished. Satisfactory performance is evidenced wherever Webster equipment has been installed.

To serve the coal industry efficiently, Webster engineers have constantly observed the necessity of reducing costs and enlarging profits. The preparation of your product to demand a higher market price can be accomplished through up-to-date equipment. Your requirements may call for miscellaneous items or a complete new tippie, but, regardless of the size of your needs, Webster offers you an opportunity to obtain the best.

The knowledge and experience of Webster engineers is available to you without cost. See that your plant is up-to-date and enjoy the satisfaction of greater profits.

Sturtevant Rock Dust Screen

Throughout the country mines are adopting rock dusting to eliminate explosions. Before adopting it in YOUR mine select your rock pulverizing and screening equipment with care. Your selection will make all the difference between successful and unsuccessful application of rock dust.

Sturtevant Rock Dust Units

are made by Specialists of forty years' experience in the manufacture of this type of equipment. When you place this equipment in your service you take advantage, at the same time, of the service of Engineers thoroughly equipped to give you expert assistance in rock dusting operations.

Fineness of grinding, capacity of equipment and low cost

of rock dust produced is most important.

We supply you with either the entire "dust plant" or any unit thereof.

We advise you on your needs and help you select your machines, erect your plant and, if you wish, send a Sturtevant Engineer to operate the plant for you.

Get the facts complete. Our latest "Rock Dust" Bulletin will reach you by return mail.

## Orient, Lynch, Now Valier!

*8664 tons in a day, a new record*

A NEW WORLD'S RECORD was set Nov. 25, when the Valier Coal Co., in Southern Illinois, hoisted 8664 tons in 7 hr. 51 min. from a single shaft.

This beats the Orient mine record, (Chicago Wilmington and Franklin Coal Co.) of 8218 tons, made in March, 1922, and the Lynch, Kentucky, record (U.S. Coal and Coke Co.) of 12,880 tons, made Feb. 12, 1923 (but from two openings).

Coal hoisted in making all three records was undercut with

### SULLIVAN IRONCLADS

At Valier, 36 out of 39 continuous cutters in use are Sullivan A.C. Ironclads, equipped with 7½-ft. cutter bars, Tipturn trucks and self-winding reels. Most of these machines are 5 to 7 years old.

### SULLIVAN Roller Bit Sharpeners

—each served by a Miller automatic oil forge, sharpen all the mining machine bits used at Valier. During November, only 1.2 bits were sharpened for each ton of coal cut. Two men operate both sharpeners and forges.

In making this record, 662 hand loaders filled 1920 cars, holding 4.51 tons each. The 600 cars made 3.5 trips each, on the average, traveling more than a mile each trip. The coal was dumped into a rotary dump at the bottom and lifted 660 ft. to the surface in 15-ton skips. 156 railroad cars were needed to haul away the day's output.

This record is no fluke, since on Nov. 26, 7763 tons were hoisted, and the average for December to the 12th was 7460 tons. (See Coal Age, Dec. 11, 1924).

Whether your mine is a record breaker, or of more moderate capacity, you can count on Ironclads to do their full share in your organization to keep production up, and costs down.

*Ironclads, Bulletin 79-DC*

## Always Full Quota Production With Ball Bearing Motors on Coal Cutters

**R**IGHT through every shift this coal cutter does its full quota of work.

Reliability and endurance—these factors are essential if equipment is to stand up and give low-cost operation in the hard service of mining.

Skayef Self-Aligning Ball Bearings on the motors increase efficiency and guard against electrical troubles. Dust and grit are effectively excluded by sealed housings, which also prevent lubricant leakage on motor parts.

# Applying "GUNITE"

with the "CEMENT-GUN"  
in the mine of the

## Lehigh & Wilkes-Barre Coal Company

When the "Cement-Gun" isn't busy applying rock-dust, or "mudizing" your haulageways, it can be used as in these pictures from this big anthracite mine, to "gunite" (with sand-and-cement) the ceilings (also the walls) of underground pump-rooms and other chambers; also to fireproof and protect roofs, walls, shafts, entries, timbering everywhere in the mine.

Let us tell you all about the many uses for the "Cement-Gun" in your coal mine property.

THE CEMENT-GUN

# From End to End

## A Real Mine Locomotive

**EVERY** part of the Baldwin-Westinghouse storage battery locomotive, from the sturdy barsteel frame to the smallest motor detail, is built to serve the user unfailingly and to give the greatest mileage from one battery charge.

### Barsteel frame:

This strong frame construction is an aid to ventilation and gives ready access to all parts of the chassis for inspection, lubrication or repair.

### Motors:

The slow speed motors are specifically constructed for mining service.

### Control:

Field control of the motors saves power by cutting out resistance except on first and second speed points.

An ample clearance is provided between the motors and the roadbed.

The battery crate is mounted on rollers to facilitate its removal.

Heat treated gears of high grade material add to the efficiency of the locomotive.

For complete information, address the nearest district office of either company.

# Westinghouse

# Reduce Shut-Downs

*with Westinghouse Automatic Switching Equipment*

**A**FTER you have paid a lot of good money for motors and locomotives why keep them standing useless because of mistakes of carelessness resulting in needless shut-downs when using a manually operated board.

Automatic switching equipment can't make a mistake. It can't throw a running breaker in ahead of a starting breaker. It can't hold a starting breaker in until the coils of the auto transformer have been burned out. When the windings reach a dangerous temperature, it automatically shuts down the station until the danger is over. With automatic switching equipment a breaker can't be closed until the short circuit has been removed. Excessive heatings and overloads are taken care of automatically. Positive protection is always assured.

Replace the possibilities of human mistakes with mechanical certainty by specifying Westinghouse Automatic Switching Equipment for Substations.

# For the Mine

*Two large Class "PRE" Compressors installed in a large South American Copper Mine*

## An I-R Air Compressor

When you install a compressed air plant you count on making a permanent investment. You buy high efficiency and mechanical superiority on the basis that in the long run it will save money.

The Ingersoll-Rand Company builds only machines of the high grade you insist on having.

Class "PRE" electrically driven compressors, such as are installed in the above plant, will maintain reliable air service. They are doing this with less horsepower input per cubic foot of air delivered than is otherwise obtainable.

I-R Compressors are built in over 1000 sizes, types and capacities.

## Throwing Out Rotaries — Installing S. & D. Automatics

**Why? Because the Tremendous Saving Has Been Proved!**

This company operates two mines, and one of them has been equipped with "Automatics" for four years. They are now changing the other mine from rotary cars to "Automatic" Drop-bottom cars. Why? Because they KNOW it will pay. Their records PROVE that the cost will be saved in a few months—and then big dividends flow in.

AN AEROPLANE VIEW SHOWING THE NEW TIPPLE AND THE OLD TRACKS

A CLOSE-UP VIEW OF THE 600-TON STORAGE BIN TO BE FILLED AUTOMATICALLY BY THE AUTOMATIC CARS

Formerly they dumped four rotary cars at a time by machinery. Now they will have continuous operation without machinery. The "Automatics" are ten inches lower, and have a larger capacity. Proved and tested beyond question.

# **1000 tons a Day from a few Acres of Territory**

It requires probably 200 acres of mine territory, average, to produce 1000 tons of coal per day; if this same tonnage can be produced from a very few acres of working territory—a very material saving in cost can be made.

Many operators are alive to this fact and are using concentrated mining methods by employing MOVOR Conveyors—the only underground conveyor with small interspersed drive units.

Write us for facts about the MOVOR Conveyor.

# 160<sup>to</sup>480% Dividends from investments in automatic pump control

160

480

This is for the man who likes the compound curves in a dollar mark and who revels in dividend figures. For this financially minded man we have a story as amazing as it is true. The story of an investment that will, in most cases, yield from 160% to 480%. And it isn't a stock selling yarn either.

Here is the essence of the thing.

In certain cases centrifugal mine pumps can be made to operate automatically thus doing away with the usual pump runner and saving his wages. The savings vary according to wage rates, the number of shifts of men used, etc., but in general, operating charges are reduced sufficiently to pay the installation cost in six months or less.

The method used to make the pumps self-operating is a patented system that has been amply tried out and there is abundant evidence that the plan is practicable and dependable. The apparatus used is as simple and easily understood by the operating force as the usual electrical equipment and pipe fittings found around a mine. This equipment was made especially for mine service, by mine pump specialists and is giving entire satisfaction and producing profits for a number of mine operators.

*Full details of this remarkable means of saving money will be gladly furnished.*

**BARRETT, HAENTJENS & CO.**  
Hazleton, Pa.

A typical automatic pumping station installed at one of the collieries of a large and well known anthracite coal company.

MANUFACTURED IN THE HEART OF

A GREAT MINING REGION

## A mark— and its meaning

**Y**OUR favorite automobile tire is marked, your hat has the maker's imprint, your clothes the tailor's label.

This means that the producer is proud of his product, he sponsors it—he is sure of the satisfaction it will give.

For the same reasons Super Service Cord and Cable have an identifying mark. The name is an integral part. Every twenty feet the words "SUPER SERVICE" are embossed on the surface—easily felt and distinguished.

All Rome Super Service Cords and Cables are so marked, so you'll be sure of the genuine, the only rubber sheathed conductors vulcanized in steel molds under tons of pressure—and built for "Super Service".

The "Super Service" family covers a complete range of types and sizes—some small enough for a dentist's drill, to large cables two and one half inches in diameter—with every mining requirement included.

# There's no Joy without TIREX

All Joy Mechanical Loaders are equipped with Tirez Portable Cable. The makers of these efficient machines have standardized on this tough, flexible, long lasting Cable.

The non-inductive 60% rubber armor of Tirez Cable cannot become charged nor wear through as do cables with braided or woven coverings. This explains why Tirez has been selected for use with these up-to-date loaders.

There's no cable made which stands up so well against the continuous dragging and yanking about inevitable when operating portable underground equipment of this nature.

For loaders, undercutters, drills, gathering locomotives, you can't beat Tirez service.

All sizes are furnished in special lengths as ordered. Full particulars on our entire line of Tirez Cords and Cables will be sent you at once, upon request. Let us know where we can reach you.

## Use this equipment to reclose feeder circuits and get maximum output

Add up the increases in your output if electric power were kept on your feeder circuits every possible moment and you have a measure of the principal advantage of G-E Automatic Reclosing Feeder Equipment. An exact calculation would be impossible, but a little study will show:

- Production can be increased by a continuity of electric power at the machine under normal conditions.
- Production can be increased by keeping electric power on main lines in case of a disturbance on a feeder.
- Production can be increased by eliminating delays incident to reconnecting an opened feeder circuit manually.

Which means that unless you already have Automatic Reclosing Feeder Equipment you have this opportunity to increase your output and your profits. Talk this over with representatives from our nearest office or send for information.

# "U.S." TAPE

## *The Right Tape for Every Job Around the Mine!*

Every mine electrician knows the importance of buying good tape—tape that is uniform in quality, high in tensile strength, and free from imperfections and pinholes. That's why experienced electricians always specify "U.S." Tape.

There's a complete line of "U.S." Tapes—a type for each particular use:

"U.S." Splicing Compound—A "Relio" splice is there to stay—a solid, waterproof joint, without heating. Scientifically compounded, easy to handle.

"U.S." Holdtite Friction Tape—Heavily coated on both sides with a high grade black rubber compound. For general electrical work.

"U.S." Armature Friction Tape—High quality white rubber friction, one side only of very thin closely woven sheeting.

*There are also five other special "U.S." Tapes*

## *The Sextette from Lucia, Ky.*

I've been caught in some tight jams already fooling around electrical equipment, but the biggest thrill that ever rattled itself up and down my spinal column was provided in the No. 2 Mine of the Acme Coal Company at Lucia, Ky. Keep your seat and I'll tell you about it. I drops off at this place by invitation one Fall morning and locates the G. M. up on the tippie with the Superintendent, where the two of them are directing the installation of a new loading boom.

"This survival of the fittest propaganda got you steamed up too?" I inquires after we had traded greetings.

"Isn't it the truth?" he smiles. "No kidding, we got to do things around here if we are going to remain out of the class of operators who are sitting around waiting for miracles to happen and provide juicy markets like we had after the big war."

"Wait until I dig up the 'Super,' Foreman and Electrician," he commands, "and I want to get your opinion on what we are going to need in the way of sectionalizing equipment."

A few minutes later the party is assembled and we make tracks for the inside. Well, it develops during the jaunt that they have been

### *The Circuit Breaker with Brains*

experiencing plenty trouble with low voltage coming from one overloaded section compounding itself with other sections carrying legitimate loads. Putting a stop to that is duck soup for us.

Finally we pull up in front of a room off one of the South entries, some mile and a half from the out-

side. Up at the face a machine runner and his helper are fighting a cutter bar putting up a game but losing battle. While we are crouching there the six of us are suddenly bathed in a shimmering green light. There fifty feet from us the cable covering had burned off from the crowding that machine armature had been giving it, and a six- or eight-inch arc was blazing in an atmosphere of suspended bug dust. Right away I get visions of the Wife and Kiddies cashing in my insurance policies, as I momentarily expect to have several tunnels drilled through my liver.

I turned to the "Super" and see him trying to hide a pair of knees shimmieing like a barn door in a cyclone. I get plenty kick out of the entire proceedings before the arc is extinguished, and the General Manager suggests maybe we have seen all we want to inside.

When we reach the surface again, the Boss tells me they have been figuring on our stuff for several weeks, but he knows he is going to get it now from the safety standpoint alone. "A breaker set down in that section to open on a low current value would never have permitted that arc to get started," he says.

And he was right!

# Rails!

In Small Lots  
As Well As Large

**T**HERE is a class of rail buyers, occasionally in need of only small tonnages, who are paying a premium on their purchases elsewhere because they believe that we do not seek their patronage.

We maintain a large organization to give efficient service on small orders. Our tremendous volume gives us unequalled buying power and saves our clients money regardless of the tonnage required.

Immense stocks at strategic distributing points provide complete assortments near you. This adds a saving in freight to our already unbeatable prices.

Next time you need rails, let us know your requirements. We guarantee the same prompt, efficient service to all.

Joy Mine CAR LOADER, 42-inch gauge, loaded less than 1,000 tons. Price on request. Also one SHORT WALL MINING MACHINE, Class S. A., No. 5021. 250 volts D. C., 1921; 18 months service.

Real Estate Trust Bldg. Philadelphia, Pa.

**A mine boss says about Beard:**

"I am delighted with the books.  
They are far more than I was ex-  
pecting—superior to all others."

That's what Martin R. Bryant of Terre Haute, Ind., said about the Beard Books.

A man of experience—a man who knows what mining men want and need—recommends the Beard Library as the one great set of mining books that will help any coal mining man into the biggest and best jobs in the field.

Take this opportunity to see the Beard's Mine Examination Questions and Answers. We send the books to you for free examination. Just put your name and address on the coupon and mail it today.

## Mine Examination Questions and Answers

A combined reference and home-study set  
3 volumes—\$7.50 payable \$2.00 a month

Beard tells you everything you want to know about coal mining. He explains clearly everything you have to know to pass an examination for the position of mine foreman, mine inspector, fireboss, assistant foreman, hoisting engineer, safety inspector, and so on.

The three fact-packed books give you complete and up-to-the-minute information about air and gases, explosions, safety requirements and methods, mechanics, engines, hoisting, drainage, pumping, ventilation, timbering, instruments and every other detail that the mining man has to know.

Ambitious mining men are using the Beard books to fit themselves for bigger jobs at better money. But hundreds of others who have big jobs are using the books as reference helps to aid them in solving the problems that come up every day.

If you are looking ahead to better things in mining—if you want to advance yourself and be as good as the best of them—if you want a help that will make you absolutely fearless in tackling any kind of a coal mining proposition—then get hold of Beard.

Examine it free first—your decision can be made later.

## 6- Eliminates hand weighing

The Streeter-Amet Weighing and Recording Machine replaces the inefficiency and uncertainty of hand or dial weighing at the tippie with the rapid, absolutely correct, and up-to-date method of machine weighing.

The Streeter-Amet Machine operates entirely automatically. The exact weight of each car or hopper is permanently recorded. Cars can be accurately weighed at the rate of 20 per minute.

Both operators and miners profit by the accuracy which the Streeter-Amet insures. Production is increased, disputes eliminated and the waste and loss due to slipshod methods done away with.

## EGYPTIAN

Shaker Screen Eccentrics

THE EGYPTIAN SHAKER SHAFT ECCENTRIC was invented because such an eccentric was an absolute necessity. Already it has demonstrated its superiority at a number of large mines where the original tippie equipment had to be replaced. Egyptian Eccentrics do *not* bind and break, as do ordinary eccentrics where there is a slight misalignment. It is self-oiling, built of highest grade materials to stand the hardest service.

## Good-by to Clinkers

Scottsdale Grates are specially designed to maintain clean fires at all times, without any cleaning through the fire doors with its attendant loss of operating efficiency.

An easily maintained clean fire means that the boiler is working at high efficiency all the time, instead of only attaining good operating efficiency by fits and starts between periods of choked up fires and cleaning.

Extraordinary quality iron, cast in special heats, prevents warping and twisting troubles. Bar design gives highest percentage of air space without any weakness of individual grates or grate fingers.

Clinkers and ash are removed from the fire by the cleaning action of the grates, not through the fire door with slice bar and poker

# MARION

MINING MACHINERY

## Examine any of these 5 New McGraw-Hill Books for 10 days free—

1. **Lubin—**  
**MINERS' WAGES AND THE COST OF COAL**  
Institute of Economics Series.  
320 pages, 5½x8, \$2.50 net, postpaid.  
An inquiry into the wages system in the bituminous coal industry and its effects on coal costs and coal conservation. The book analyzes the peculiar wages system that has been developed in the bituminous coal industry and shows how this system has affected the earnings of the miners, the cost of producing coal and the exploitation of our coal resources.
2. **Reed—**  
**BITUMINOUS COAL MINE ACCOUNTING**  
221 pages, 6x9, illustrated, \$3.00 net, postpaid.  
An outgrowth of the universally recognized need for a uniform system of accounting and cost-keeping in the bituminous coal mining industry.
3. **Shurick—**  
**COAL MINING COSTS**  
515 pages, 6x9, illustrated, \$5.00 net, postpaid.  
This book helps you to answer the question: "What is the most economical way to mine coal"? It shows actual costs of doing work in representative mines throughout the country.
4. **Young—**  
**ELEMENTS OF MINING**  
Second edition, 671 pages, 6x9, 282 illustrations, \$6.00.  
A comprehensive view of the mining problem offering an immense mass of material compressed into a clearly written and well illustrated treatment.
5. **Palmer—**  
**PRACTICAL CALCULUS FOR HOME STUDY**  
443 pages, pocket size, flexible, 186 illustrations, \$3.00 net, postpaid.  
This book is for the man with limited mathematical training who has need for a working knowledge of calculus and its practical applications. It shows just what kind of problems can be solved with the aid of calculus and explains thoroughly and clearly how.

## One threaded part

The Sure-Grip is the only trolley clamp ever designed having but one threaded part and that will automatically align with the trolley wire in any direction. And because the threaded part is not exposed it cannot rust up or become battered. Sure-Grip can easily be removed from old workings and used again and again.

The Sure-Grip Clamp incorporates the simplest and most effective method yet devised for compounding gripping pressure on the trolley wire. Just tightening one nut attaches the Sure-Grip firmly to the hanger face and grips the trolley wire with a hold that only a heavy fall of slate can break.

## THE SHAY

### Is the Standard of Comparison

WHEN geared industrial locomotives are discussed, the standard of comparison, by which others are judged, is the Shay.

"We believe and know," writes the owner of one company, "that the Shay is the best and surest power on the market. It is very economical in operation and handles a larger tonnage than any other kind of power on the market today."

Nearly half a century ago, the original

Shay Geared Locomotive was designed to operate under great difficulties.

Built particularly for hard service, the Shay Geared Locomotive has proven ideal for operation in almost inaccessible places, on sharp curves and steep grades, with temporary unballasted track.

Before you choose new engines for your work, compare them with the strip mine standard—Shay Geared Locomotives.

# PRIMM

## OIL ENGINES

### Fuel Economy— Greater Than Ever

**T**he PRIMM Oil Engine has always been noted for great fuel economy, advanced design and trim appearance. When we produced the type "BU" PRIMM Engine a few years ago it was met with acclaim by engineers as the finest type of low compression oil engine yet produced.

OUR engineers did not then consider their task ended—they still experimented—they still sought to effect improvements. It seemed they could do no more for the type "BU" PRIMM Engine was indeed a wonder.

Recently their efforts were rewarded. They made several new discoveries which have been incorporated in the new type "SBU" PRIMM Engine—the greatest of them all.

Greater simplicity of design, vastly increased fuel economy and an exceedingly handsome appearing PRIMM Engine is the result of their efforts. To those who are interested in this most efficient of prime movers we shall be pleased to send a descriptive bulletin.

## Leschen Wire Rope Is Dependable

When you buy Leschen Wire Rope you are not experimenting, for its ability has been proven by its service record. For heavy mine hoisting and haulage and for steam shovels, mining machines, etc., we recommend Hercules (Red-Strand) Wire Rope because its unusual durability enables it to work with marked economy under such conditions.

# Fast, safe mine "rail- roading"

## CENTRAL Mine Track Equipment

Today's mining problem is a problem of getting out coal at lower cost, and good track work is a first essential in this new drive for efficiency and economy.

CENTRAL frogs, switches, crossings, turnouts, switchstands, etc., are doing their part by making mine "railroading" safer—even at high speeds—eliminating delays, tie-ups and other troubles that cut down production figures. Smooth, continuous transportation requires expertly designed and well-built equipment at the vital haulage points and CENTRAL products are giving this type of service at many mines.

No track equipment gets harder service with less upkeep than mine trackage.

This is just one reason why better quality is built into CENTRAL frogs and switches, and why they stand all the pounding of heavy locomotives at high speed coupled to strings of loaded cars.

## A Super Tower

Generosity typifies the design and construction of Caldwell Structural Towers. To provide the strength and sturdiness that have marked the unusual success of this type of tower for heavy loads and great heights we have spared no precaution in material or workmanship.

This tower is built of heavy structural shapes thoroughly laced and riveted together by the most modern scientific engineering methods. It is built for steel or wood tanks in capacities from 15,000 gallons upward.

Send for Catalog.

Caldwell  
TANKS AND TOWERS

**Track work** in yards and haulageways of coal mines cannot be too rigidly inspected. If it were a temporary thing there would not be anything vital in the efficient moving of coal. All "Cincinnati" Trackwork is built to stand the gaff. Inspectors find less track trouble where it is employed. Try it on some important line and see whether this is fact or fable.

*The Little Giant  
Electric Coal Drill*

Completely described in Bulletin 895—the booklet that will help place your production on a basis similar to those described. Write for your copy.

*The Little Giant Electric  
Coal Drill and Mounting.*

## Crowd Development —and Increase Production

**A**T THE Illinois operation shown above nine No. 472 Reversible Little Giant Mounted Electric Coal Drills are in continuous use in driving entries and cross-cuts from entries. One drill is assigned to a seven-man gang, consisting of five loaders, one chain-machine runner and one driller. The earnings are pooled and divided equally. Since installation these men now earn in ten days what formerly required thirteen days' work, with a resultant increase in production of approximately thirty per cent. The rate of drilling is two feet per minute.

In a new large operation in Southern Illinois two miles of development were made in three months—a record-breaker. Chain machines were used for undercutting the coal, No. 472 Reversible Little Giant Mounted Electric Coal Drills for shothole boring, and mechanical machines were used for loading. This record was made possible by the use of Little Giant Coal

Drills, which reduced the idle time of the chain and loading machines to a minimum. Rate of drilling, two feet per minute. One man with a drill completed nine headings, consisting of three shotholes each, in one day. All drills used twenty-four hours (three eight-hour shifts) continuously with but slight maintenance cost.

Little Giant Electric Coal Drills are playing a most important part in speeding up development programs. They supply the missing link in the mechanical production of coal, and take from the miner the last tedious, back-breaking manual job.

Little Giant Electric Coal Drills are not in the experimental stage but have been developed as the result of extended field tests in practically every principal coal-producing field in the world. Let us demonstrate what they can accomplish in your operation.

## Crush Your Coal

With a Link-Belt Crusher always available, your slow moving sizes can be quickly reduced to meet changing market demands.

For reducing run-of-mine coal, Link-Belt Crushers have been built with capacities up to 1,000 tons per hour. Made in two roll, single roll and four roll types, designed to produce the various commercial and domestic sizes with least amount of dust or oversize.

All Link-Belt Crushers are ruggedly built, and are correctly designed to meet the conditions under which they are expected to operate, thus insuring satisfactory service.

Write to our experienced engineers. They can help you produce high grade coal suitable to present demands. Also ask for Book 333.

Sturtevant Rock Dust Screen

## Get the facts about this complete Rock-Dust Outfit!

Throughout the country mines are adopting rock dusting to eliminate explosions. Before adopting it in YOUR mine select your rock pulverizing and screening equipment with care. Your selection will make all the difference between successful and unsuccessful application of rock dust.

Sturtevant Rock Dust Units

are made by Specialists of forty years' experience in the manufacture of this type of equipment. When you place this equipment in your service you take advantage, at the same time, of the service of Engineers thoroughly equipped to give you expert assistance in rock dusting operations.

Fineness of grinding, capacity of equipment and low cost

of rock dust produced is most important.

We supply you with either the entire "dust plant" or any unit thereof.

We advise you on your needs and help you select your machines, erect your plant and, if you wish, send a Sturtevant Engineer to operate the plant for you.

Get the facts complete. Our latest "Rock Dust" Bulletin will reach you by return mail.

# Proper distribution of ROCK DUST is the important consideration

That's the kind you get  
with the **CEMENT - GUN**  
Trade Mark

The distributing nozzle  
will reach locations well  
away from track facilities—in fact, anywhere  
a hose will go.

The "dual purpose"  
outfit

THE "CEMENT - GUN"  
TRADE MARK

IS NOT A RESTRICTED  
ARTICLE AND MAY BE  
PURCHASED AND USED  
BY ANY ONE.

In order, however, to insure to  
all users of "Gunite" that they  
will obtain prompt and proper  
bids we have established a Con-  
tract Dept., and upon applica-  
tion we will be pleased to have  
them prepare estimates on your  
work.

Use the "Cement-Gun"  
for rock dusting and, at  
other times, to place  
"GUNITE" to fireproof  
and protect roofs, walls,  
shafts, entries, etc. Write  
to us—
